+ Means movement upward or to the right. — Means movement downward or to the left.

occurring first under this action had penetrated so deeply into the concrete that it conld influence the eqnilibrium of the arch. At 300 tons loading the crown had raised 2.7 (of 1/25 inch) over the position it had when loaded with 225 tons (Fig. 4 c), and 0.5 over the original position at the commencement of the experiment. The next 100 tons called forth a further movement upward in this point of 28.7.

Consequent on this movement the unloaded northern arch half (to the right in Fig. 4) which hitherto had been curved strongly, was straightened again so that the centre had raised to 1.1 under the original position when the test-load was 300 tons; afterwards the arch turned upward around the hinge and at 400 tons load the centre was 20.0 over the point where it was situated when the bridge was loaded with its own weight alone.

The angle turnings measured at the levels on the hinge stones agreed with the above-mentioned movements. The crown hinge opened first downward, corresponding to the deflection at the top and toward the finishing of the experiment upward. The sonthern abutment hinge (to the left in Fig. 4), to which the loaded bridge is attached, opened up during the whole experiment, the northern down.

The hinge stone on the northern abutment moved in all, after the agreeing measurement on the land and Rhine side, .9 horizontally and 1.0 upward and turned ¾ backward in a loading from 0 to 300 tons. At the southern abutment a similar movement to respectively 1.5 and 0.7 took place, but the result of the level readings did not agree for this abutment with the mentioned movements. The reason can perhaps be found in the circumstance that this abutment had not been separated from the walls of a building standing close by, as the leading persons thought that it was better to save the expense of that work, as no importance was attached to the behavior of the abntments during the test-loading. As a very great number of instruments (in all 41) were used, it was possible, in spite of the many different disturbances

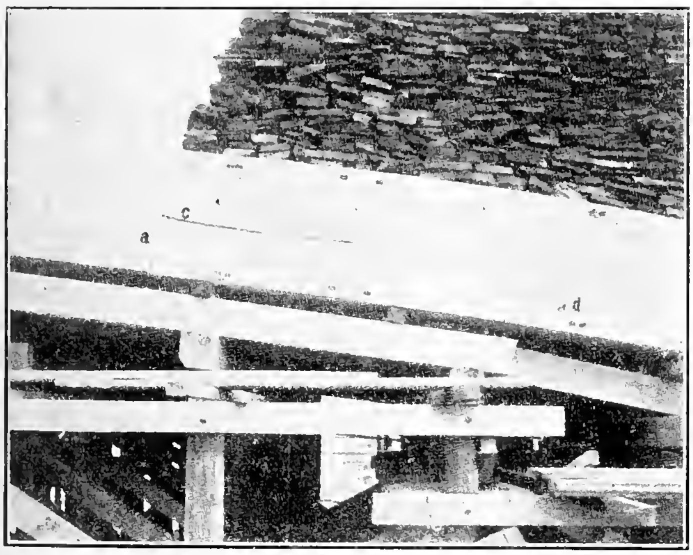

Fig. 5.

arising from changes of temperature, wind, etc., for each kind of measuring to find a sufficient number of agreeing apparatus, the reading of which could be used for comparing with the theoretical researches.

These results all aided in a determination of the pressure lines for the different loading stages. (Fig. 6). As the weight of the load and its position on the bridge were exactly measured and the specific gravity of the concrete in the arch had been found to be 2.36, the acting forces were fully known, both in regard to value and situation, and it was thns possible for each stage to draw an exactly determined pressure line, also the acting points of the pressures in the hinges had been measured. As the figure shows, the pressure line rises more and more under the loading by an increasing of the load from 0 to 225 tons, until, under influence of this load it reached the extrados of the arch. At

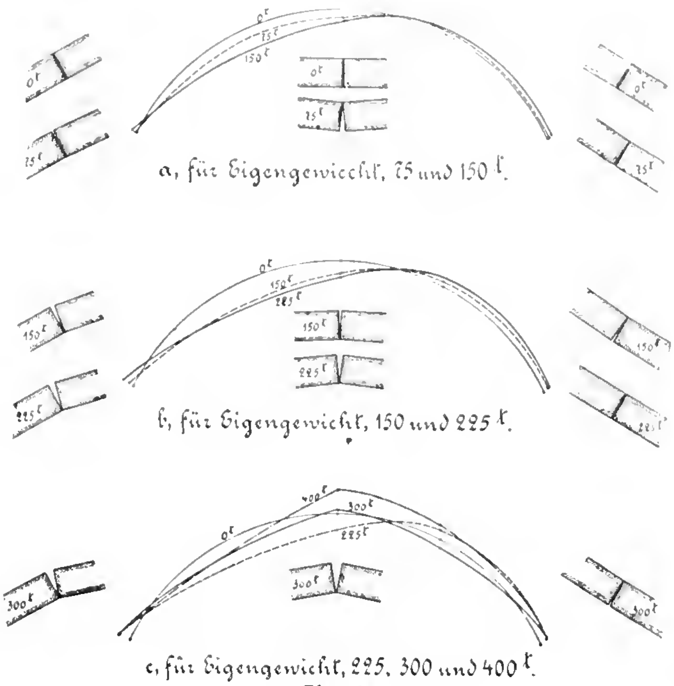

Fig. 4.

the intrados, rises corresponding to this position of the pressure line an increasing tension stress was shown. In the unloaded part of the arch the pressure line becomes more and more flat with corresponding tension at the extrados.

From Fig. 6 it will be seen that the distance of the pressure line from the centre line of the arch is essentially greater in the loaded side than in the unloaded, and greatest under that half of the steel load which is nearest to the crown; therefore, the greatest bending stress occurs here and at the same time considerable shear stresses, as the direction of the pressure line deviates so much from the centre line. The greatest unfavorable concentrated load produced such tension and shear stresses in the arch that it is not to be wondered that a poured joint, which otherwise was fully excluded from the bridge, and which accidentally was situated at the edge of the loading material, opened. The crack commenced at the intrados and was then transmitted upward into the arch and, as the statical examination shows, the crack was throughout so deep that the tension stress in the remaining concrete was 350 to 400 lbs. per square inch. When the length of the crack was equal to half of the arch thickness on the Rhine side and ¾ on the land side (300 tons load) a horizontal shear crack was visible. (Fig. 5). It was now assumed that the bridge would collapse, the thickness of the undamaged concrete being only 16 inches on one side and 8 inches on the other; but no break took place, and it was possible to increase the load by one-third up to 423 tons.

Between 225 and 300 tons the vertical crack came into full action, which can be seen from the fact that the extensometer, which was placed in the point d (Fig. 5) in the neighborhood of the crack, was suddenly unloaded, having hitherto shown increasing tension stresses. At the same time the

agreeing reading on the four deflection meters at the crown of the arch showed that this point commenced to raise. This means that the loaded part of the arch tried to straighten, and corresponding to this a considerable rolling must have taken place in the crown hinge. This was also clearly visible by the levels. By this turning the pressure was moved downward, by which a new pressure line could be figured inside the undamaged concrete and which would explain the new

equilibrium. Without the hinge the movement at the top could not have taken place and the bridge would probably have broken down before the load had reached 300 tons.

The maximum compression stress is on calculation 2,320 lbs. per square inch under 423 tons load. At the vertical crack the tension stress was 350 tons, 400 lbs. per square

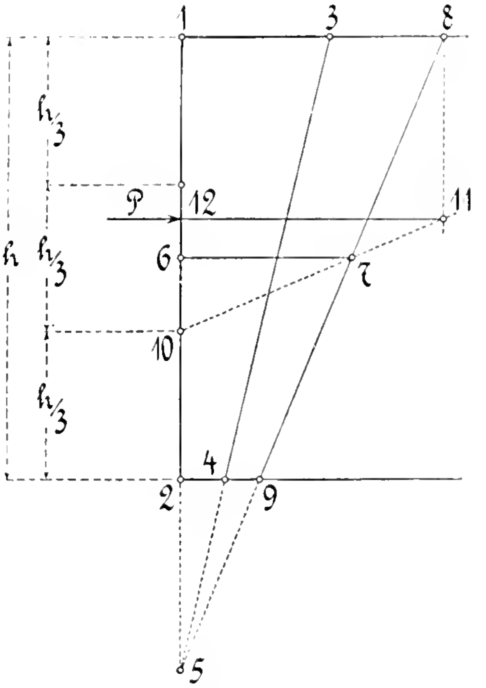

Fig. 7.

inch, and in the unloaded part of the arch the same stresses were found.

The object of measuring the elongations was to determine the position of the pressure line, the value of the acting stresses and to obtain information concerning the modulus of elasticity of the concrete. The main difficulty of those problems consisted in the circumstance that these quantities are exceedingly small, and that the modulus of elasticity is not a constant, but varies with the value of the stresses.

The modulus of elasticity was also fixed in another way independent of the measuring. Two blocks were cut out of the concrete in the arch, from which cubes were sawed with 12-inch side. For two of these not only the compression strength was measured, but at the same time the value of the decrease in length corresponding to each stage of the pressure, by means of which it was possible to determine the moduli of elasticity, thus giving a specially good occasion to test the value of the elongations, stresses and moduli of elasticity figured out after observations on the bridge itself by comparing the values directly found with those found by the cubes.

For the determination of the location of the pressure line and stresses in the arch the following method of procedure was employed:—

From the value of the compression or tension in the highest and lowest point in a section (1—2 in Fig. 7) of the arch (1—3 and 2—4) the position of the neutral axis (5) and from that the acting point of the normal force could be determined. The normal stress (6—7) in the centre line of the section was figured out from the normal force and the area of the section. The normal force could not be measured directly by means of the instruments, but must be taken from the above-mentioned pressure lines (Fig. 6) with corresponding force polygons, which can be designed exceedingly exactly on the basis of the very careful determination of the specific gravity of the concrete, the dimensions of the bridge and the position of the pressures in the hinges.

Assuming a rectilinear distribution of the stresses, the value of these can be found directly by drawing 5—7, which give the stresses 1—8 and 2—9. The acting point of the normal force (12) is located by drawing a line through 7 and the lowest third point, 10, and from the intersection point of the line 10—7 and 8—11 (1—2) a line 11—12 (6—7). The length 1—3 and 2—4 are in this case the sum of the variations in the length from the test-load and the weight of structure; these last-mentioned could not be further measured on the bridge, but should have been measured as the falsework was remote. It was, therefore, necessary to make certain assumptions in order that they might be figured.

The value of the normal force in the unloaded part of the bridge could be directly found in the force polygon, but

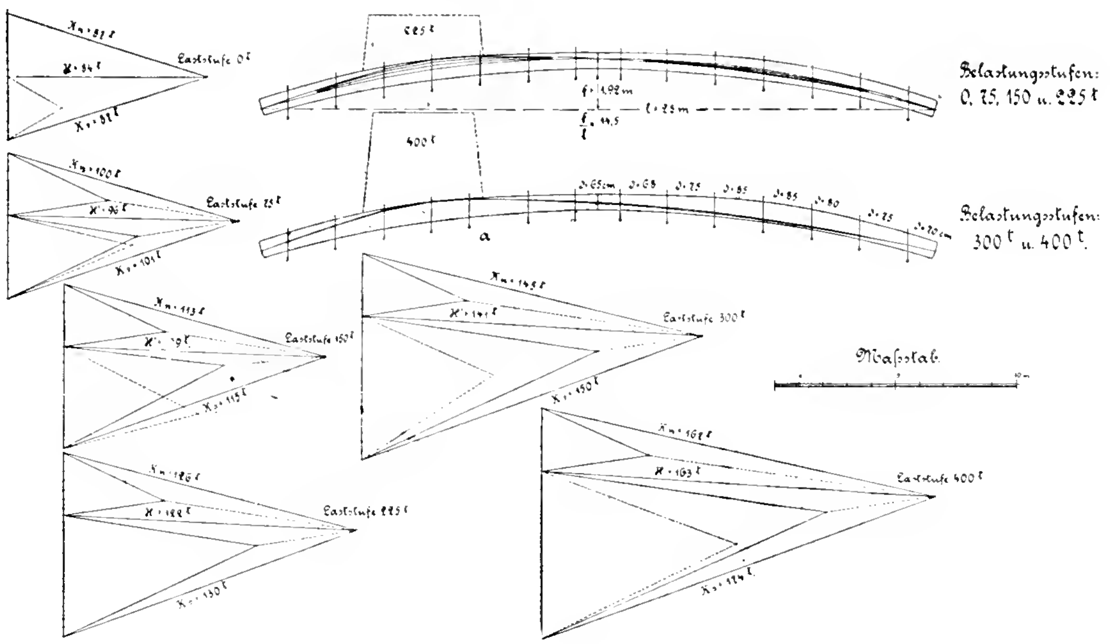

Fig. 6.

the alteration of the length must be figured out from a chosen value of the modulus of elasticity, which was fixed at 5,500,000 lbs. per square inch, after trying different values between 1,500,000 and 8,000,000. This value agrees very well with the laboratory experiments made with the cubes of the seven-year-old concrete, as shown in Table II. The compression experiments are in this case specially valuable, because the line of pressure for the dead load nearly coincides with the centre line of the arch and, therefore, only produces compression stresses.

As proof of the correctness of the situation of the pressure line and value of stresses found in this way, the sizes figured out by the statical examination serve.

reached in this case by means of the strongly concentrated load over the centre of one part of the arch was 2,740 lbs. per square inch, the concrete originally having been figured out with a permissible stress of 560 lbs. per square inch. By this five times increased stress no indication of the destruction of the concrete could be seen.

2. Although the arch was very flat and the pressure line close to the centre line, it was still possible, in this case by the special arrangement of the loading material, to develop tension cracks. As above mentioned, the tension strength was about 350 lbs. per square inch. As the tensile strength has been entirely neglected in the calculations, the structure has a further safety in this high value.

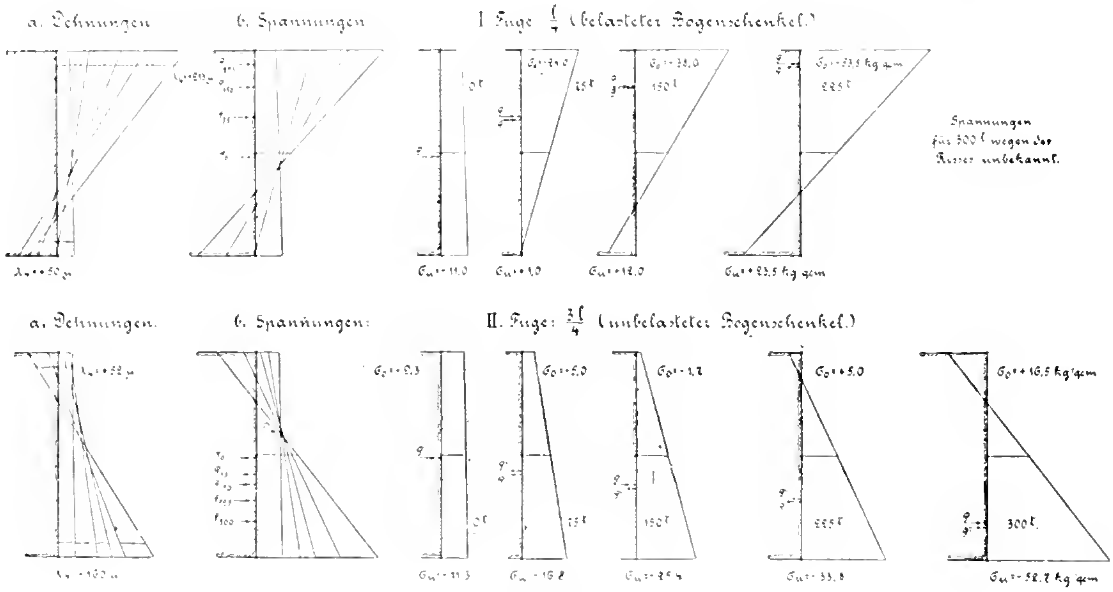

Fig. 8.

In Fig. 8. is given a graphical representation of the alteration in the length, found by Frunckle's apparatus and the hereafter calculated stresses, for one section of the loaded part of the arch (above in the Fig.) and one in the unloaded, both situated one-fourth of the span from the springing lines. Under a are given the elongations (and shortenings); under b the stresses (in kg. per c.m.^{2}). P in the diagrams means the normal load found by the experiment and P^1 the one found by the calculation. It will be noted that the stresses vary in a very satisfactory manner.

The results of the two different ways of determining the stresses are given in Table III.

As a summary of the test-loading on the bridge the following may be given:—

1. As the bridge is merely constructed to resist compression forces, the compression stresses found by the experiment are of greatest interest. The greatest value of these,

3. For giving an approximation of the weight of steel used, it may be compared with the common 23-ton steam rollers. On the same area, which was filled with steel, four rollers, with a total weight of 92 tons, could be placed; the load used by the experiment was thus $\frac{423}{92} = 4.6$ times greater than this quite exceptional loading.

The bridge, during use, has probably had a still greater bearing strength due to the distributing ability of the fill concrete over the arch and because an increase of the dead load in ratio to the live load moderates the movement of the pressure line.

4. The hinges have been very useful; without them the new stage of equilibrium could not take place, and the bridge would have collapsed under a much smaller load than it was able to carry, as it had free movement at three points.

UNITED STATES STEEL CORPORATION IN CANADA.

Mr. James A. Farrell, president of the United States Steel Corporation in testifying as to the corporation's export trade in the United States Government suit, referred to the Canadian business in part as follows:—

"Through Montreal we sell about 60,000 tons of wire product a year, sheet iron, mine rails, and sometimes standard rails, when they cannot be supplied by their own corporations. We are now supplying the Canadian Northern Railway with 25,000 tons of rails shipped by boat from Chicago and thence by rail to Calgary, where they cost $47.13, delivered.

"At Vancouver we supply much material, but the freight rate from Pittsburgh there is $18 a ton. Material from Liverpool or Antwerp may be shipped for $6 to $8 a ton. After we established our office there we found it necessary to run a steamship service there. Our ships leave about every two months, making stops all along the line. On the return we go into a general merchandising business."

INVESTIGATION OF METHODS OF OPERATING THE PITTSBURGH SLOW SAND WATER FILTRATION WORKS.

In July, 1910, George A. Johnson, consulting engineer of New York, was engaged by Hon. W. A. Magee, mayor of Pittsburgh, Pa., to make an investigation of certain features of construction and existing methods of operation of the slow sand water filtration works completed by that city in 1908 at a total cost of some $6,000,000. Mr. R. S. Weston, of Boston, Mass., was associated with Mr. Johnson on studies relating to the chemical phases of the problem.

The practical result of Mr. Johnson's investigation are set forth in the last annual report of Mr. Chas. A. Finley, superintendent of the Water Bureau. Abstracts from Mr. Finley's report follow:—

"It is noted with satisfaction that the total operating and maintenance charge for the year is almost $50,000 less than the cost of last year's operations. The total for the past year was $818,626.12; for the previous year $868,141.07. Most of this saving is due to the improved methods of operating the filtration plant, the saving in operation at this plant during the last year being about $40,000."

"The operation of the filtration plant for the past year has been attended with gratifying results from a financial and sanitary point of view, due to the fact that, with the improved methods of sand handling instituted last year, we were able to operate the plant about $40,000 cheaper than the cost of operating by the methods previously employed."

"It appeared, from an examination of the records, that the operating cost of our plant was unnecessarily bigh. It also appeared that, at certain seasons, we got unusually small yields from filters between cleanings."

"The question thus naturally divided itself along two lines:

"1st. A study of the actual operating conditions within the filters, such as methods employed for sand handling, etc.

"2nd. A study of the physical and chemical properties of the river water, for the purpose of devising methods of eliminating from the river water the causes of the excessive clogging, prior to its application to the sand filters.

"The first question has been handled and investigated by Mr. Johnson.

"The second question has been handled and investigated by Mr. Johnson and Mr. Weston, acting in conjunction.

"These investigations began in July, 1910, and extended over about eighteen months' time, to January, 1912.

"The principal changes in operating conditions within the filters were the introduction of the process of 'raking' the filters between 'scrapings,' thereby securing additional yields from the filters at less expense than by continuous scraping, and a change in the process of restoring sand from restoring by machine to restoring from open hose lines under water."

"The study of the physical and chemical properties of the river water was of necessity complicated and protracted, due to wide variation in the character of the water on account of seasonal and other changes. The investigations were continued until all the different types of water had been encountered, a large amount of data was compiled, careful study made thereof, and conclusions drawn therefrom."

"In line with the conclusions, a system for the preliminary treatment of the river water was designed, and the necessary contract plans prepared for the construction of the same."

"The result of these investigations indicates that the daily capacity of the plant can be increased from one hundred and twenty-five million gallons to two hundred million gallons without the construction of additional sand filters. The amount of water yielded by a filter between cleanings is an essential factor in the increased capacity of the plant. The prime object of preliminary treatment is the assurance of the necessary field between cleanings. With this yield assured, the rate of filtration, or the amount of water filtered daily through each filter, can be increased so as to produce a total daily yield of two hundred million gallons, and still maintain the economy of operation in sand handling."

"To arrive at this total daily capacity by slow sand filters, without preliminary treatment, under the present conditions, would require the construction of about thirty additional slow sand filters of one acre each. The approximate cost of this installation would be over two million dollars, not including the necessary land."

"The annual saving in sand handling alone is $40,000, with the plant as it now stands, and if we consider the difference in cost between the extension of the present sand filters, without preliminary treatment, and the introduction of preliminary treatment, without extending the sand filters, as developed by the investigation, said differences being, in round numbers, about $1,600,000, exclusive of land, and allow 5 per cent. annually on this saving, it amounts to $80,000, which, with the $40,000 saved in operation, makes a total of $120,000."

TRACK CONSTRUCTION ON PAVED STREETS.

At the recent convention of the American Railway Engineering Association one of the committees recommended the following practice on paved street construction:—

They recommended that treated ties should be used and should be laid on a bed of crushed rock, gravel or other suitable material, not less than 8 in. nor more than 12 in. in depth, placed in about 3-in. layers, each to be thoroughly rammed to compact it.

Vitrified tile drains were recommended to be not less than 6 in. in diameter, with open joints and leading to nearest point from which efficient drainage might be obtained or with sufficient outlets to reach sewers or drainage basins. These should be laid on either side of and between tracks, parallel with ballast line and outside of ties.

It was recommended that a 141-lb. girder rail of 9-in. depth, or one of similar section, with suitable tie-plates and screw spikes, should be used. The track should be filled in with crushed rock, gravel or other suitable material, allowing for a 2-in. cushion of sand to support the finished pavement.

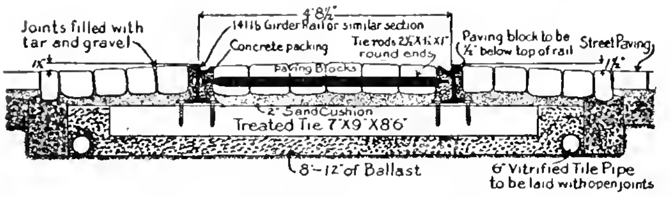
Ballast for paving foundation should be well rammed as it is installed. Two inches of good, sharp sand should be placed on top of the ballast. Paving should conform with municipal requirements, granite or trap rock blocks preferred. Hot tar and gravel should be poured into joints as a binder.

A test which may be of interest was one on cleaning stone ballast by the use of screens. The results of this test tended to show that a gang of twelve men, properly equipped with tools, would cover about 165 ft. of double track per day of ten hours, making the cost per mile of double track $640. This cost included the work of cleaning the ballast, dressing the track and disposing of the dirt. The labor charge included a foreman at $2.40 and eleven laborers at $1.60 each.

The report of the committee on buildings included a brief report on the advantages and disadvantages of various types of fright house floor construction in part as follows:—

Freight House Floors.—"Freight house floors should ordinarily be built to carry a uniformly distributed load of at least 250 lbs. per sq. ft. Except for small houses, a filled-in floor, considering the cost of maintenance, is ordinarily cheaper than joist construction. It is also advantageous, because it will carry the unusually heavy loads that sometimes occur.

"The usual method of construction consists of filling up to the required level with sand or gravel, thoroughly flushed and compacted. To ensure a dry floor, on this filling is laid a bed of ciuders about 6 in. thick, thoroughly compacted. In the cinders are bedded sleepers, preferably about 4 in. x 6 in., laid flat, about 2-ft. 6-in. centers. These and the plank above them should be thoroughly treated with creosote of zinc chloride where there is to be an additional



Recommended Track Construction for Steam Railroads at Paved Street Crossings.

wearing surface applied. With untreated timber renewal is sometimes necessary within four years, though under favorable conditions a life considerably greater is usually obtained. When no cinders are used on top of the sand the decay seems to be hastened.

"In place of cinder filling and sleepers a layer of coal-tar pitch spread upon a layer of sand over a course of concrete is being quite extensively used. This is durable and is said to give good results. Specifications for this method are obtainable from the coal-tar producers.

"Either on the sleepers, laid in cinders, or on the pitch are laid planks about 2 in. thick. With the pitch sub-floor the plank should be laid with broken joints toenailed and embedded in the pitch by hammering until the proper stability is obtained. Care should be taken to see that they are brought to an exact grade. The plank need not necessarily be toenailed with the wooden sleepers.

"To get a smooth-wearing surface on top of the plank hard maple is generally preferable. It does not splinter and it wears evenly. It has a short life when exposed to the weather. It is growing scarce and getting expensive. Beech is often sold for maple, they being difficult to distinguish. It is somewhat darker in color and it splinters more. Birch is softer than beech or hard maple, but does not splinter so readily as beech.

"Gum, especially tupelo, is recommended as a substitute for maple, and it probably will, to some extent, displace it. It is darker in color and somewhat softer, but it wears evenly and it does not splinter much more than maple. Thorough seasoning is particularly essential. There is a large supply of gum in the South and its use for floors should be extensive.

"Under most conditions, the best floor can be had by laying the top floor diagonally, putting the plank lengthwise and the sleepers crosswise of the house, without any bearing on the side walls. Inequalities in settlement of the floor are then less liable to make trouble, the plank can be laid with minimum expense, and the top floor gives the best results after considerable wear. This costs for the top slightly more for laying and more for repairs. Where there is a pronounced amount of trucking in one route it is sometimes thought desirable to put the flooring parallel to this trucking but where the amount of traffic warrants it would seem best to put a runway of steel plates.

"Wood block pavements may be used in place of the board floor. They are best used on top of a concrete sub-floor, with a 1-in. sand cushion between. With wood blocks care should be taken to obtain sufficient expansion joints, as many floors have failed from a lack of this precaution. One inch for 50 ft. is about the correct amount. Care should also be taken to avoid the use of creosoted blocks where flour or similar articles which are easily damaged by odors are handled. There is also a chance of such damage from tar used in the expansion joints. Zinc chloride is for this reason recommended as a preservative for wood blocks when used for freight house floors. Zinc chloride is cheaper than creosote, and in a freight house the blocks will not suffer from the leaching which takes place when they are exposed to the weather, the main objection to the use of zinc chloride for treatment of cross-ties and paving blocks. It is almost impossible to get this kind of floor as smooth as a maple floor, but if properly laid it tends to wear smooth. It is adapted to points where wear is especially severe, such as are due to the handling of castings and heavy machinery. Its main advantages are in the ease with which it can be repaired. The blocks are ordinarily made of pine. It would seem that gum blocks would be better. Maple blocks are also used, but are expensive.

"Concrete has been used successfully where the wear is not too severe. There is a good deal of chance of damage by falling freight, and its use must be restricted to places where there is little chance of castings and similar articles being handled, unless the top surface is carefully made of the best of hard aggregates. Under such conditions excellent results have been obtained.

"A concrete sub-floor protected by a layer of asphalt mastic will give excellent results. It will cost more than the concrete floor, but it will not chip and scars made in its surface soon disappear. It is not so cold as the concrete floor and has been used for this purpose with success.

"Asphalt blocks properly made would seem to have some advantage for this purpose. They should make a smoother floor than the wood blocks and can be more easily repaired than the mastic floor."

RAILWAYS AND CIVIC WORKS AT REGINA, SASK.

The following civic works will be carried out this year:—Street railway extensions, $825,000; gas plant investigations, $25,000; trunk sewer (48-inch), $240,000; waterworks extension, $200,000; storm sewer mains, $60,000; power plant (new one), $425,000; electric light extensions, $250,000; health and scavenging equipment, $117,000; road making, $22,000; fire hall and motor equipment, $60,000; footbridge over Canadian Pacific Railway tracks, $35,000; winter fair auditorium, $134,000; police station and court, $180,000; hospital addition, $125,000; complete subways, $37,000; remodel market building, $7,500; domestic sewer mains, $630,000; domestic water mains, $420,000; paving, $580,000; paving (under old by-law), $550,000, (debentures sold); concrete sidewalks, $115,000; collegiate extension, $100,000.

As a railway centre Regina occupies a fine position. All three of the great transcontinental lines operate in and out of Regina. The Canadian Pacific Railway was the pioneer, but the Canadian Northern and the Grand Trunk Pacific has entered into an agreement with the city council to spend $1,000,000 on the erection of a large hotel, which will contain 275 sleeping rooms. This railway will also erect a large station at a cost of about $500,000. About eight hundred feet of train sheds will be built adjoining the station so that all trains arriving in the city will be under cover.

SOME WATER SUPPLY PROBLEMS OF THE WEST.*

By R. O. Wynne-Roberts, M. Inst. C.E., M. Can. Soc. C.E., F.R. San. Inst., etc., Consulting Engineer, Regina.

Owing to the gentleman who had arrauged to read a paper to-night finding he had to leave the city, and would, therefore, not be able to fulfil his engagement, and, as the time was too short for others to fill the breach, it is to be hoped that the following note will furnish topics for discussion:—

Every country, district and town has water supply problems to solve. It is rare to find nature so generous as to furnish abundant, pure supply of water without leaving some difficulty, more or less great, for the engineer to surmount. We have only to study the conditions in Canada, which, perhaps, possesses the most bountiful supply of water of any country, to observe that a number of towns and cities are combatting with one difficulty or another. The supply of water is either difficult to procure, or it is limited in quantity, or it is not pure.

Whilst in the East and extreme West of Canada there is abundance of water, the problem in many places in the Middle West is to find a copious and pure supply, and it will be well to consider why it is often so difficult.

The author has during his career had a number of water problems to deal with, but when he visited Regina and was asked by the corporation, through your president, who was then City Commissioner, to conduct investigations with the view to augmenting the supply, he found new conditions, which had to be carefully studied.

Geological Formation.—One of many interesting features which had to be studied was that of the geological formation of the country, and in this connection it may be useful to describe the agencies which primarily contributed to form the topographical features of this part of the country.

The present surface is entirely of glacial origin. When the first great ice invasion of the glacial epoch moved southwards the surface of the country was doubtless much more rugged than it is to-day, and the valleys possibly drained in other directions. The great sheet of ice, many hundreds of feet in thickness, advanced slowly southwards, stripping loose material, crushing and levelling rocky hills; stones, gravel and mud became frozen to the ice, and increased the power of the glacier to wear down other rocky excrescences, etc. Enormous masses of crushed rock of many kinds were thus picked up and conveyed from the northern parts across this country into the United States. When the climate became warmer the ice gradually melted back, and huge streams of water, which flowed down from the ice sheets, and brought with them great quantities of detrital material, depositing the same in uneven masses, filling up valleys and forming the plains and hills which constitute the principal features of the prairies.

Where this great ice sheet halted from time to time terminal moraines were formed.

The second ice invasion again changed the surface of a large part of the country, disturbing the deposits left by its predecessor and redepositing the same.

These ice sheets advanced across Canada into the United States in the form of a huge tongue, and the glacial deposits can be found over vast territories. These masses of glaciated material vary in thickness, magnitude, shape, character, and distribution, and were laid in a most chaotic manner. The districts around Regina, for instance, are from 1,900 to 2,400 feet above sea-level, and about 600 to 1,100 feet above the Lake Agassiz, which was formed in the glacial period. This lake and other glacial lakes extended westward [illegible]s the Elbow on the South Saskatchewan River.

The channels or ravines cut out by the stream[illegible]g from the ice sheets have been gradually or partially [illegible] in by sand, silt and gravel washed out of the mor[illegible] deposits, building up the gentle slopes and flat plains [illegible]tween the banks. During the ages that have since elapsed the streams have eroded passages through these outwash plains, and in places undercutting the beds of drift, thereby tapping the underground water-bearing stratas and causing springs to appear on the surface.

The fine silt or mud, composed of disintegrated cretaceous rocks, which were carried by the ice sheets, formed the flat or very slightly undulating land surface of the prairies, which constitute the major portion of the country south of Regina. This material, called till, consists of pulverized rock forming impalpably fine clay mud, often intermixed with gravel, boulders and rock. This till, bluish-grey in color, although oxidized on the surface and underneath for a few feet to yellowish clay, is to be found over the country, extending to the Central States of America. It usually underlies the gravel deposits, and forms a more or less impervious substratum. The upper portion of this till is commonly softer and easily dug, while below it there is a sudden change to a hard and compact deposit, locally called hardpan. The probable cause of this (according to Mr. Upham) was the pressure of the enormous weight of the ice sheet upon the lower and older till, while the upper till was dropped loosely as the ice melted. The boulders, which are more or less plenty on the ridges and in valleys, are generally granite, gneiss, and schists brought from the northwest, and also limestone—the latter, being softer and more easily crushed, has been largely reduced to gravel, etc.; hence it is that the substratum consists mostly of limestone and clay.

It is important to note that the glacial till, consisting of a matrix of clay with pebbles and boulders, and, forming a more or less watertight mass, has intermingled and interbedded with it in a most extraordinary manner, and often lying above and below it porous water-laid sands and gravels, which constitute the water-bearing strata. In many places these beds of sand and gravel lie between two beds or till of different epochs of formation, but in a greater number of districts gravel beds of varying depths, thickness and character are to be found under the clay bed drift. It is, however, not possible to trace these beds for a great distance. The calcareous matter has been leached out of the older formation, but in the more recent accumulation it virtually remains without change; consequently, the water obtained for the latter beds are heavily charged with mineral salts.

The surficial layer of drift is generally open and fairly loose, with the result that water percolates rather freely into the subsoil. Owing to the uneven manner in which the glacial materials were deposited and to the undulating nature of the surface, it is inefficiently drained; there is a plexus of pools, sloughs, and swamps. The drift is often saturated nearly or even to the surface; hence it is that so many farmers are able to obtain a fairly abundant supply of water from shallow wells. In times of drought, however, the water table will be considerably reduced, and in some instances it will probably sink below the bottom of such wells. This is also the main reason why sloughs appear to dry up in seasons of drought.

In the case of the outwash sands and gravels to be found stretching out from the moraines, these beds, being very porous, readily absorb the rain falling upon them.

Sand dunes are found in some places, like Pilot Butte. These were formed by sand from the plains drifting with the winder and heaped up in cones or dunes or drifting sandhills. The time of formation of these dunes was probably

* Paper read before the Regina Engineering Society.

soon after the recession of the ice sheets and before vegetation had spread over their surface.

Rainfall.—The question which arises after ascertaining the areas of the possible watersheds is the quantity of rain falling on such sheds, more especially in prolonged periods of drought.

As a fairly typical example, we might consider Regina district. There are two rainfall observation stations on which the rainfall in the Regina district may be relied upon. These are the North-West Mounted Police barracks and Qu'Appelle. These, however, do not accurately represent the rainfall on the watersheds east and north-east of Regina, because the stations are lower than the waterheds in question.

By analysis of the recorded rainfall at these stations the mean annual rainfall is computed at about 16 inches. The next step to take is to ascertain the rainfall in any three driest consecutive years. The above-mentioned records were carefully examined, and it was found that it amounted to about 10.4 inches, or 65 per cent. of the mean annual precipitation.

Evaporation.—The problem that has to be next investigated is that of evaporation that takes place on the surface of the water and land. Part of the rain percolates into the ground to feed the water-bearing strata springs, etc., and sustain vegetation, another part is lost by drainage off the surface of the land into the streams, and a portion is evaporated. In the West, however, snow remains on the ground for months. The ground is frozen to a considerable depth; consequently, not much water percolates down to the substrata during winter. It must be remembered that evaporation goes on throughout the winter; when the spring arrives, much of the remaining water, in the form of snow and ice, when melted will drain away. Furthermore, in summer, some of the water which has percolated into the ground is absorbed by vegetation and then transpired into the atmosphere. There are, however, several depressions in the land surface, such at kettle-holes, etc., which retain water until it disappears into the ground or is evaporated. The phenomena of evaporation is an interesting one, and it is to be hoped that the Government will some day arrange for careful observations over a prolonged period to be made, for it has a very material influence on the question of water supply, irrigation, agriculture, etc. In general terms, evaporation is a product of many conditions, such as temperature of the air and water, duration and intensity of solar rays, the dryness and velocity of the air, etc. Evaporation increases with rainfall, but is much more uniform in districts of large rainfall, and in districts of low rainfall it is relatively high. So, in years of drought especially evaporation constitutes a very important factor in the problem of water supply.

The United States Government has conducted a long series of evaporation on the Salton Sea, California, where it was found that the evaporation ranged from 51 inches in 1908 to 69 inches in 1910. In Ohio it was 46 inches. It may be estimated that from the surface of water it is approximately 50 inches in the West, but what is lost by evaporation from the land surfaces is not possible to estimate at present.

Yield.—The yield from watersheds varies in every case, owing to the difference in physical features, such as mountains, valleys, as contrasted with flat or undulating prairies, rocky catchments as compared with porous plains, luxuriant vegetation, trees and foliage on the one hand and "prairie wool" on the other.

In the case of Regina water supply, after taking into consideration the many conditions and approximate similarity with water sheds in the States, it is estimated that by laying extensive collection pipe lines and sinking wells about one and one-quarter inches out of ten inches rain in the three driest consecutive years can be secured, but it cannot be assumed that a similar yield can be obtained from any other watershed in the prairie provinces, for it might be exceeded or be far less, as eveyrthing depends on local features.

There are available for Regina about 200 square miles of watersheds, and at the above rate it is estimated that about ten million gallons can be collected and delivered into the city.

Tapping the Supply.—Having ascertained what extent of catchments are available, the minimum rainfall in driest years, estimated the losses by floods, evaporation, absorption, and what is collectable, it then remains to be decided how best to tap the supply.

This depends on several conditions, such as topography of the district, substrata in which the water is expected to be found, inclination of the water-bearing stratas, etc.

While the author was conducting the investigations into the question of augmenting the water supply, he visited over two hundred farmers, and from them obtained information as to the nature of the stratas through which they sank wells and in which they found water; he also inspected over 800 square miles of country, and by this and other means in many places was able to locate the existence of water-bearing stratas, the direction in which they dipped, and the area of the watersheds. The author recommended sinking wells in Boggy Creek, where works had already been started, as it was the lowest point in that part of the catchment which could be utilized, and also the laying of collecting pipe lines in various directions.

Wells.—Authority was obtained to carry out the recommendations, and in April, 1912, the first well was sunk 108 feet, when a large volue of water overflowed at a height of twelve feet above ground. This well has continued to overflow at the rate of about 150,000 gallons per day. Up to the present time eighteen wells have been sunk, of which ten are overflowing, five are choked and three were unsatisfactory. The choked ones can be cleaned when necessary. Some of these wells are five inches in diameter and the rest are seven inches. They vary in depth from 65 feet to 192 feet. The underground pressure and the velocity of flow in some instances were too great to maintain a constant supply, as the large volume of water gushing out of the wells induced too great a current in the water-bearing strata, and this caused sand and other materials to be conveyed with the stream and choke the wells referred to. To overcome this difficulty it was decided to sink other wells in their immediate vicinity so as to relieve the pressure, and this has been partly successful. In some cases quicksand and soft clay cause trouble.

The stratas through which the wells were sunk were as follows:—

No. 2.	Feet.	No. 5.	Feet.	No. 17.	Feet.
Clay	6	Clay	38	Mud and clay.	40
Coarse sand	20	Clay and gravel	5	Sand and gravel	2
Fine sand and clay	8	Gravel	30	Clay and sand	13
Fine sand	13	Yellow sand and quicksand	17	Fine sand	17
Gravel and sand	3	Clay and hardpan	10	Quicksand and clay	60
Sand	21			Hard clay	25
Hardpan	4			Clay and sand	18
Depth	75	Depth	100	Depth	175

The author, in October last, was consulted by the Carlyle town council in connection with the augmentation of the supply of water. After making an inspection of the district around, the council was advised to sink a well on a certain

patch of land. This well was sunk in April, 1913, and at a depth of 192 feet water was found under conditions which were predicted in the report.

Quality of Water.—Well water in the prairie districts is charged with lime salts, caused by contact with different kinds of limestone. This is common to almost all well waters in the West. As already stated, when the ice sheets were passing over the country a large quantity of rock was transported. The harder rocks survived the process of crushing better than the soft rocks; hence it is that in some districts hard rock boulders are to be found on the surface. It is estimated by the geologists that about 90 per cent. of the surface boulders are of hard rock and 10 per cent. soft rock, but in the substrata the proportions are reversed, and we find 90 per cent. of gravel is limestones of various kinds.

Water readily absorbs salts and gases, and, consequently, in its passage through the soil and different stratas, mineral salts are being absorbed. In addition to salts, water absorbs gases, and, as carbonic acid gas is present in the air and in the ground, it is taken up by the water, and this increases its solvent powers. When the water finds an outlet to the atmosphere, such as in the form of springs, some of the carbonic acid gas is lost and it becomes less heavily charged with lime and, consequently, a limited natural softening process takes place.

The water as supplied to Regina, for instance, contains carbonate and sulphate of lime and carbonate and sulphate of magnesia and other chemical constituents. These salts cause the water to be "hard," and the problem is how best to soften it. Hard water used in boilers causes sludge and scale to be formed, and these in time not only reduce the efficiency of the boiler, but also tend to cause overheating of the plates and other troubles.

The hardness of water is usually divided into two classes, namely, temporary hardness and permanent hardness. As already explained, water absorbs lime salts more readily when it contains carbonic acid gas. By heating the water, this gas is driven out and the carbonate of lime held in solution by means of such gas becomes insoluble, and its greater part, together with magnesium carbonate, is precipitated and forms sludge. Temporary hardness is that part of the total hardness which is precipitated by boiling.

Boiling will not have the same action on the sulphate, chloride or nitrate of lime or magnesia, as these salts remain soluble. Permanent hardness represents these salts as well as the parts of the carbonates of lime and magnesia not precipitated by boiling. Temporary and permanent hardness, however, are relative terms, to denote the characteristics of hard waters.

Apart from the use of hard water for industrial purposes, it is of importance to consider it from the domestic viewpoint. One part of carbonate of lime decomposes 6.12 parts of stearate of sodium, and, as soap usually contains only 60 to 70 per cent. of stearate of sodium, about 9.5 (say, 10) parts of soap are required. Consequently, if 100,000 gallons of water per day are consumed in washing, cleaning and other purposes, in which operations soap is necessary, it is a simple calculation to ascertain the consumption of soap necessary to produce lather.

Each part (or one pound) of carbonate of lime per 100,000 parts (or pounds), which is equivalent to 10,000 gallons of water, requires about ten pounds of soap to obtain lather. This is equal to 100 pounds per 100,000 gallons. Water obtained from wells in the prairies contains, say, 20 parts of carbonate of lime per 100,000, so that the total theoretical consumption of soap will be 2,000 pounds per 100,000 gallons.

Soap is retailed at about ten cents per pound; therefore, one ton of soap will cost about $200, or about $2 per 1,000 gallons.

We will now consider softening of the water by means of lime. Carbonate of lime, $CaCo_3$, is nearly insoluble, but when carbonic acid gas is present, soluble bicarbonate of lime is formed. Dr. Clark's process, which has been in operation all the world over, in one form or other, for about half a century, consists of adding quicklime or slaked lime to the water, with the result that the active lime at once combines not only with the excess dissolved carbonic acid in the water and forms the practically insoluble carbonate of lime, but also robs the bicarbonate of lime of its semi-combined carbonic acid, so as to effect practically a total precipitation of all the lime present as carbonate. The active lime thus effects exactly the same result as would be produced by boiling.

In softening water by adding lime, theoretically, 0.56 parts of quicklime is required to remove each one part of carbonate of lime in 100,000 parts of water. In practice, however, more quicklime is required. Adopting the same basis for calculation, as is the case of the soap consumption, each part (or one pound) of carbonate of lime per 100,000 parts (or pounds), which is the same as 10,000 gallons of water, requires 0.56 parts or pounds of quicklime to remove the carbonate of lime. This is equal to 5.6 pounds per 100,000 gallons. The water contains, say, 20 parts of carbonate of lime per 100,000, so 112 pounds of quicklime are necessary. With lime at one cent. per pound, the cost of softening such water is $1.12 per 100,000 gallons, or 12 cents per 1,000 gallons. The actual cost will probably be nearly twice as much. It will thus be observed that softening by lime is, theoretically, about eighteen times cheaper than by soap.

Prairie water, however, as already stated, contains other salts than carbonate of lime, and we will see what it means to adopt a softening process to reduce them to an economical minimum. That will mean the adding of quicklime as well as soda ash.

Assuming that prairie well water contains:—

20 parts per 100,000 of calcium carbonate.
3 parts per 100,000 of magnesium carbonate.
15 parts per 100,000 of magnesium sulphate.

The quantity of quicklime to remove the calcium carbonate with the theoretical amount already mentioned, 112 pounds per 100,000 gallons.

The theoretical quantity of soda ash necessary to remove most of the magnesium carbonate will be 37.6 pounds, and to remove the magnesium sulphate 130 pounds per 100,000 gallons.

The cost will, theoretically, be:—

112 pounds of lime at one cent per pound....	$1.12
167.6 pounds of soda ash at three cents......	5.03
Total	$6.15

The cost of lime and soda is, therefore, equal to about six cents per 1,000 gallons, but in actual practice it will be more. To this must be added the cost of labor, supervision, capital charges, etc. As the cost is high, it is desirable to ascertain to what extent the hardness can be reduced, having regard to our local conditions with respect to cost of labor and materials. But this the author will not follow further at present.

Before any softening scheme can be undertaken with any degree of confidence and satisfaction, it is essential to obtain results of mineral analysis of the water to be treated, which is different to sanitary analysis. It must be clearly understood that the foregoing figures are only approximations submitted to illustrate the nature of the problems confronting the engineers in the West.

Before leaving the question of water softening it will doubtless be interesting to refer to another process, which is now before the public, and that is the Permutit process. Permutit is the trade name of an artificial zeolyte produced by a process invented by Dr. Gans, of Berlin. Germany. This material is granular in form, much line coarse, grey sand. It is usually placed between layers of fine gravel in a filter bed or tank. As the water passes through the permutit and exchange takes place. The sodium in the permutit exchanges with the calcium and magnesium in the water, and by this means the hardness of the water is reduced to zero. When the permutit has lost its power of exchange, or, in other words, it is exhausted, it can be revived by saturating it with a solution of common salt. In this case the sodium in the salt is exchanged for the calcium absorbed by the permutit, and, when the exchange is complete, the filter is washed and is ready for softening a further quantity of hard water.

There are a large number of water softening plants on the market, all worked on the same principle, but differ somewhat in details in the method of proportioning the lime and soda, and in the general arrangements, but it will be impossible in the space of this short paper to discuss them. The selection of plant suitable for Western waters so as to obtain uniform results at as low a cost as possible requires full consideration.

Sterilization.—As all waters in the West are more or less liable to pollution, it is necessary to adopt some means of sterilization. In this case there are several ways of sterilizing water, such as by ultra-violet rays, by chlorination, and by ozonation. The most popular method at present of sterilizing water is by adding a very small proportion of hypochlorite of lime, often as little as half a pound per 100,000 gallons, or one-half part per million. The quantity of sterilizer required depends, of course, on the quality of the water to be treated. This is a subject which would alone suffice to occupy an evening, and, consequently, can now only be touched upon as indicating one of the problems to be dealt with.

Filtration.—Towns situated near rivers or streams would seem to be much more fortunate as regards water supply than those remote from such streams; but it often occurs that the river water is polluted and muddy, or both, and problem is to effectually eliminate the mud or pollution. This is done by means of coagulation, settling basins, filters, etc.

In the West, climate, especially in winter, is rigorous; the temperature at times falls as low as minus 50 degrees Fahrenheit. Open settling basins and filters are, consequently, out of the question. They must be covered, and this increases the cost considerably, and some means has to be found by which the cost may be kept at a reasonable minimum. Temperature stresses are often greater than the stresses due to weight of water or earth, and, as solid masonry possesses elasticity only to a small degree, reinforced concrete would appear to be more suitable for works which are subject to expansion and contraction, due to a great range of temperature. The steel embedded in the concrete tends to distribute the stresses and prevents concentrated contraction or expansion. The author has observed on an excellently built dam, exposed to a less range of temperature than is experienced in the West, fractures in two or three places from top to bottom, splitting huge masonry blocks. In reinforced concrete structures, correctly designed and carefully built, such fractures are not so localized, owing to the greater distribution of stresses by the steel reinforcements.

Settling basins and filters can, of course, be built in reinforced concrete. It is a question worthy of careful consideration whether rapid mechanical filtration is more suitable and economical for muddy and impure waters drawn from rivers.

Water containing comminuted clay mud is difficult to treat without adding some coagulant. In New Orleans, clay was held in suspension in Mississippi water after many weeks' storage in settling tanks.

At Lorenzo Marques (Delagoa Bay) water very heavily charged with clay is satisfactorily clarified and purified by means of coagulation and filtration.

Prefilters are adopted in many places, especially on the European continent, to remove heavier sediment, and so relieve the ordinary filters of much work, and also secure greater purification.

There are some parts of the West where it is stated to be practically impossible to obtain water. Efforts have been made in some instances to discover water by means of electrical and other devices, and it would be interesting and instructive to know the results.

Having regard to the difficulty of finding an adequate water supply in portions of this province, and its consequent retardent effect on the development of the same, the Dominion Government has had plans prepared for drawing water from the South Saskatchewan River for distribution in the districts in question. In this scheme it is proposed to construct a dam across the river to generate electrical power for pumping the water through the conduits over the high banks The provincial government also, it is understood, is making investigations into this matter. This action on the part of the government only emphasizes the points already referred to in this paper with regard to the problems in connection with water supply in the West.

Distribution.—The last problem to be discussed in this paper is that of the distribution of water in the towns and cities. It is noticed, according to the press, that almost every city in Canada has a problem to solve in respect to the system of distribution mains. This question constitutes an important feature of city planning, for without city planning it is almost impossible to satisfactorily provide for the future. It may seem strange to include the supply of water in city planning, but it must be remembered that it concerns everything which will contribute to the material progress and prosperity of a city.

In the West, perhaps more than elsewhere, the growth of the population is so great that it is difficult to extend works of public utility collaterally with the expansion of the city. A village often grows into a town and then into a city in a remarkably short time, and it taxes its financial resources to provide water, sewers, streets, lights, etc., to all parts of a district as it is being built upon. But it is not a difficult matter to plan out a town or city ahead of its expansion and design the system of distribution mains and other works, so as to be sufficient for a city many times its present size, without incurring undue financial burdens on the present ratepayers. It will doubtless be recognized that it is much more costly to alter and enlarge works than it is to provide ample dimensions at first, especially in a country where towns increase so rapidly.

The actual facts are, that the authorities generally provide only for the present. Mains are, therefore, laid from time to time, and these are extended in various directions without first carefully considering what will be the ultimate result.

This possible development was foreseen by your president when city commissioner, and his successor, City Commissioner L. A. Thornton, with the author, submitted a joint report to the Regina City Council recommending a scheme of distribution mains, such as will suffice for a much larger city.

It was pointed out in the report that when any water mains are being laid in any part of the city they should conform as closely as possible to the sizes and directions shown on the plan attached to the report, so that whatever is done will ultimately constitute a part of the complete scheme.

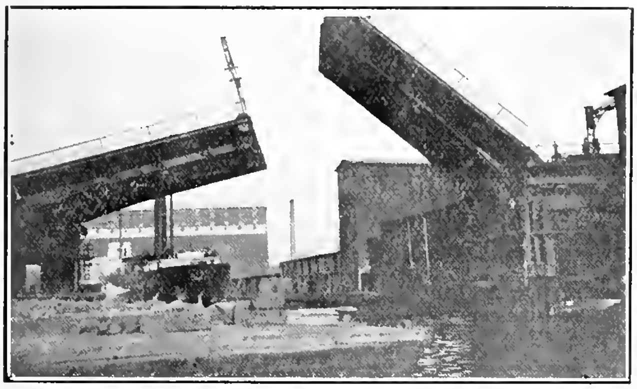
Although engineers have no greater insight into the future than other persons, they can at any rate calculate the probable population in different sections of the city and design works of adequate capacity, so that when any portion is being carried out from time to time, it will form a part of a satisfactory scheme of distribution.

In conclusion, there are doubtles many other problems which could with profit be dealt with in this paper, but time and opportunity have not been sufficient, yet it is to be hoped that what is presented will furnish ample topics for criticism and discussion.

SPEED OF DRAWBRIDGE OPERATION AND ITS VALUE.

By Henry Grattan Tyrrell, C.E.

The required speed of operation depends upon the location and natural conditions. Where the river banks are high, so that nearly all river travel can pass under the bridge, the speed of operation for the few openings required for tall-masted ships is not so essential as when the deck is near water, making it necessary to open the bridge for all kinds of craft, big and little. In remote places for only occasional service, a slow movement, perhaps by hand-power, may be permissible, as in the Nyasaland vertical lift bridge in South Africa, which is operated by eight men in twenty-five



Sixth Street Bascule in Milwaukee; One of the Most Recent Designs.

minutes, or the Hooghly pontoon draw at Calcutta which requires fifteen to twenty minutes to open it and as long to close it again. On the other hand, in busy cities and especially at low-level crossings, it is important to economize every second of time, and to install the most rapid operating machinery.

Swing bridges usually take from four to six minutes for a complete cycle, and this is facilitated by having the bridge so designed that the ends are reversible, and the bridge can then follow a boat around and continue moving in one direction. More time is needed if the bridge must open in one direction and after coming to a stop and waiting for the boat to pass, start up motion again in the reverse direction for closing. By continuous moving in one direction the swing bridges on the Tyne at Newcastle (1877) made a complete circuit in 2½ to 3 minutes. Bascules have the quickest movement, for the amount of lift can be suited to the size of boat, while a swing must perform a complete revolution for a craft of any kind, either large or small. The modern bascules in Rotterdam can be opened in 15 to 20 seconds in calm weather, and the experience with these structures in Holland cannot be surpassed, since that country is so extensively provided with canals and waterways. The speed is affected to some extent by the presence of snow and water on the floor, for these influence the balance and necessitate a little more power and time, and this provision becomes more serious in the colder districts, such as in lower Quebec, or in Western Canada, where the winter is more severe.

The importance of rapid operation in cities, such as at Vancouver in British Columbia, can best be appreciated by an example. A bridge which has 100 openings per day, of five minutes each, will delay street travel for a total period of eight hours, or one-third of the time, five to six hours of which will be during the day, or nearly half the working hours.

The economic speed of operation, and the investment which is permissible to secure it, or to reduce delays for any particular case, can readily be determined. Observation must be made of the nature and amount of travel on both street and river, and the number of water craft that would require a bridge opening. The value of public time which can be saved by the introduction of more adequate machinery will represent the interest on the investment which is permissible. The matter is easily understood by an example. The saving to the public by placing the bridge high enough to avoid too frequent openings is illustrated by one of the openings bridges at New York. The old low bridge, only eight feet above the water, had been opened on an average of forty times per day, while the new one, with an under clearance of 24 feet, needed opening only twelve times per day, though the new and heavier bridge had a slightly slower movement than its predecessor.

The saving of public time by the higher bridge was $4,000 per year, which is equivalent to 4 per cent. on $100,000. It was therefore economical to spend $100,000 additional on the new bridge to secure the greater under clearance and fewer openings.

These conditions apply wherever opening bridges are used, such as along the Canadian system of canals from lakes to the Atlantic, and on the proposed new canals from Georgian Bay eastward.

From forthcoming treatise entitled "Movable Bridges." By H. G. Tyrrell; 800 pages. Ready for press.

CAPITAL CHANGES.

The following companies have increased their capital stock: Dunlop Tire and Rubber Goods Company, Limited, from $993,000 to $1,300,000, by the issue of 3,070 shares of new preference stock of $100 each; the Walkerville Light and Power Company, Limited, from $25,000 to $100,000, by the issue of 750 shares of new stock of $100 each; the Hercules Garment Company, Limited, from $20,000 to $50,000, the increase consisting of 300 shares of $100 each; the Security Lumber Company, Limited, from $500,000 to $750,000, the increase consisting of 2,500 shares of $100 each; the Maritime Nail Company, Limited, from $250,000 to $3,250,000, the increase consisting of 30,000 shares of $100; the Carritte-Paterson Manufacturing Company, Limited, from $50,000 to $300,000, the increase to be divided into 2,500 shares of $100 each.

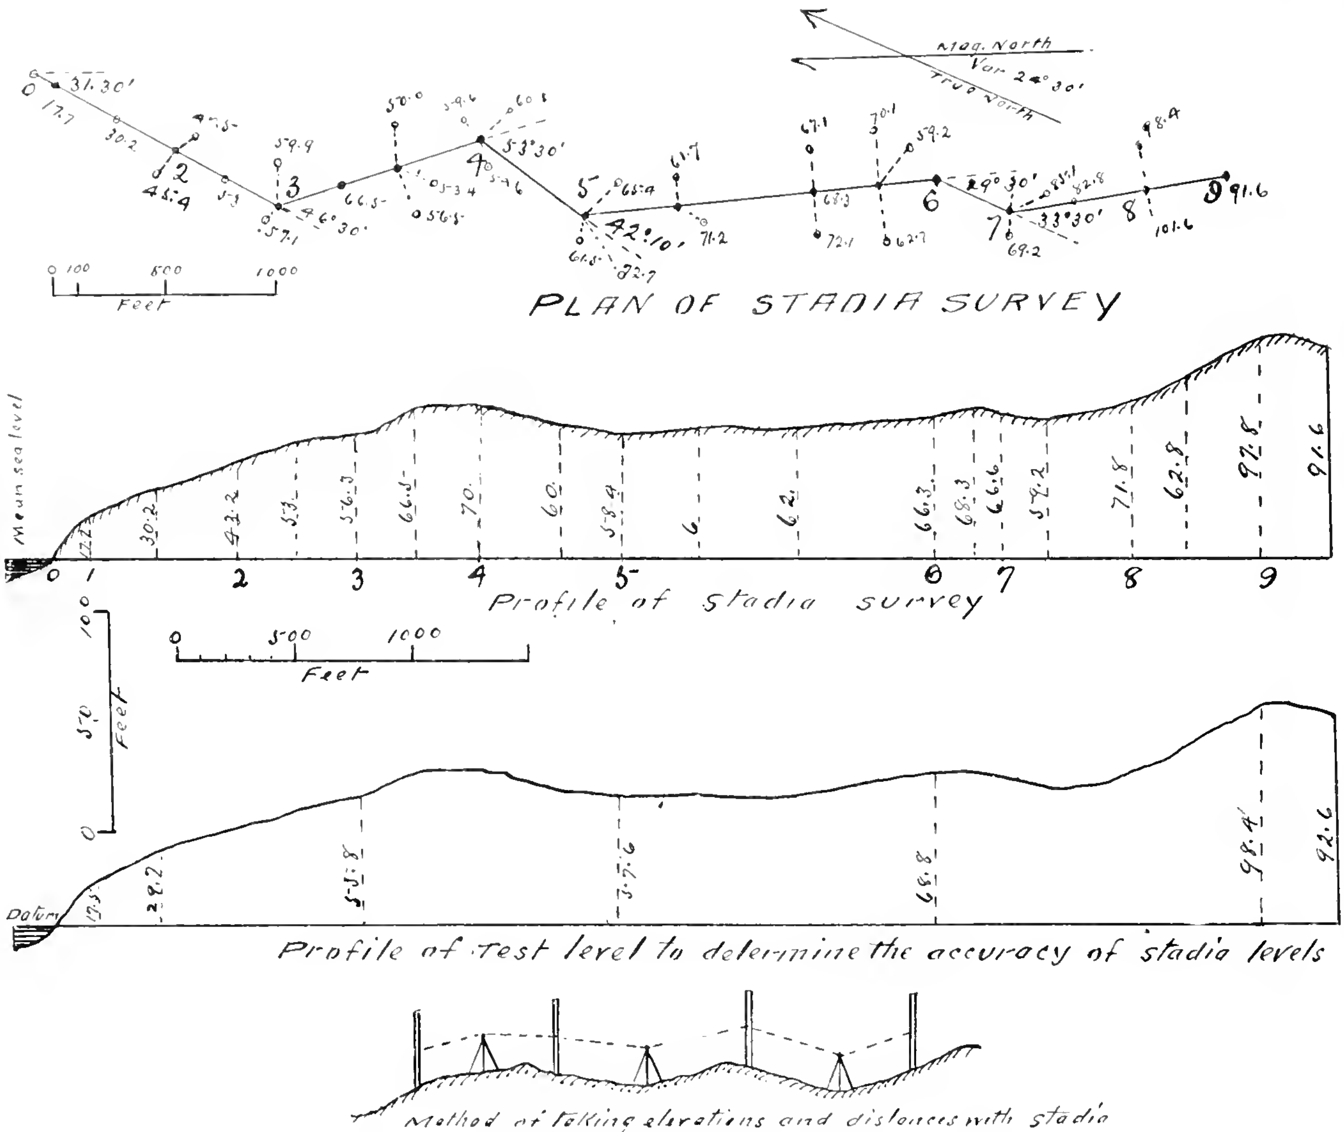
PRELIMINARY RAILWAY SURVEYING BY MEANS OF THE STADIA.

By J. A. Macdonald.*

In the present case the survey was started from mean sea level, that is, a point in the Gulf of St. Lawrence; not that the railway was intended to run to the sea (which it yet may) but in order to obtain a reliable and definite datum. At this point of starting there was quite a bank to the water's edge at mean tide. The transit was set up on the bank above and very carefully levelled. The rod was held at approximately the water's edge when it was judged by calculation, as well as observation, to be mean tide. The vertical angle to the rod was, as shown in the field book, —14°55 and the distance read on the rod .71. These data corrected gave an elevation of 17.7 feet and a distance of 65 The bearing by the compass was N. 31.30 E. This bearing was used. By an observation it was found that the difference between the magnetic bearing and the astronomical bearing was 24°30′, that is, the needle varied 24°–30′ west. Both are shown on the plan.

The next sight forward was S. 31.30 W. and an azimuth of 211°30, the distance by rod reading was 3.20, the angle elevation +2°15′, which equalled a distance of 319 and a difference of level, or elevation, of 12.5 on a point on the tangent. From stat. 2 to stat. 3 the same bearing, S. 31.30 W., was produced, and points taken on either sides of the line to determine the topography. A point on the tangent 211°30 gave elevation 53. (above sea level). Left, 142°00′; distance, 1.13 (reduced to 109); vertical angle, +2°15′; difference of level 4.3 and elevation 47.5. Right, 312°30′; distance, 1.10 (reduced to 109); vertical angle +1°10′; difference of level, +2.2; elevation, 45.4. A hub, of course, was set at stat. 2. At stat. 3, a lock sight being taken, points were taken on either side before deflecting the angle. A point left 97°00′ gave distance 1.82 and difference of level 3.6; right, 291°00′, 83 for distance and 8′ vertical. Another point, right, 328°00′, gave rod reading 1.10 (reduced to 109); vertical angle 1°00′; difference of level, 1.8. A deflection angle of 46°30 was made and the same procedure gone on with. A form of the field book with notes for the beginning of the survey is appended.

In this way the topography of the country was obtained to great exactness. Only about half the number of men were required on the line than if a regular transit, level and topographic parties were maintained, and equal results were produced, though not so rapidly.



Characteristics of Stadia Surveying.

* Department of the Interior, Ottawa.

To test the accuracy of the stadia levels, a run of regular levels were made on the first portion of the line, a profile of which is given. It was found that the variations between the stadia calculations and the level were very little when the stadia observations were calculated by the regular methods.

This surveying with stadia means much work in camp in reducing and calculating the sights, but in a country where there is not much bush it is a rapid and satisfactory method. The regular party can be divided into two stadia parties for running the preliminary line. For exploration lines in new country it is an excellent method. The map-plans and profiles well illustrates the methods employed.

Station	Def. Angle	Bearing of Tangent	Points taken	Azimuths	Distance (Stadia reading)	Distance corrected	Vertical Angles	Compt. Diff. of Elevations	Elevations	Remarks
1	31°30	N.E. 31.30		31°30	.71	65	−14.55	−17.7	17.7	Mean Sea Level
			Tan	211 30	3.20	319	+2.15	+125	30.2	
2		S.W. 31.30	Tan	31 30	3.06	305	+2.30	+13	43.2	
			Tan	211 30	2.70	269	2.05	+9.8	53.0

One locating engineer, in particular, on the National Transcontinental Railway, several years ago, when the writer was working on the line, employed the stadia for most of his preliminary lines, and for all of his exploration lines. He divided his party into two units, one in charge of the transitman and the other in charge of the leveller. As a stadia party only requires about one-half the number of men to carry on the work satisfactorily that a transit party needs, he was in this way enabled to cover twice the area of ground than if he employed the transit alone.

At that time, in the wilds of Northwestern Ontario nothing comparatively was known of the country north of the Canadian Pacific Railway. There was no map of that wide range of country from Winnipeg east to Lake Nipigon. The country around Lake Nipigon was partly mapped. East of Lake Nipigon to Lake Abitibi was little known nor further east. The railway explorers sent in by the Grand Trunk Pacific in 1904-05-06, entered a dense wilderness, and were under great disadvantages. On entering this wilderness these hardy engineers were like a ship in mid-ocean without beacon, buoys or landmarks, and like the sailors on board ship, were forced to take astronomical observations for latitude, longitude and azimuth to find their bearings and make a start mapping the country by means of exploratory surveys. It was on these surveys that the value of the stadia was first prominently brought into play in Canadian railway surveying. The country west of Lake Nipigon was covered by lakes large and small. One could scarcely go a mile without striking a small lake. The larger lakes had to be traversed in order to map it. Here the stadia was used entirely. Very rapid work in the traversing of lakes was accomplished with the stadia. In this way was the country mapped and made possible for the final location.

WATER WASTE INVESTIGATION.

Water waste in our Canadian cities is a familiar subject, but we have not heard so much about waste in the smaller towns. W. D. Gerber, consulting engineer, of Chicago, presented a paper on this subject before the Illinois Water Supply Association, an abstract of which we publish herewith.

The curtailment of water waste is particularly desirable in places which secure their water supplies from deep or artesian wells. The continual draft on the wells has lowered the ground water level to such an extent that serious problems are presented in getting the water to the surface. With a less severe demand on such wells we may reasonably expect their life to be materially lengthened.

Those towns which draw their supply from rivers or other surface waters must, of course, treat such water to render it suitable for domestic purposes. These treatment plants, besides the treatment tanks and filters, usually have connected therewith large clear water reservoirs for the storage of a considerable quantity of the treated water. The capacity of the treatment plant, including the reservoir, is usually designed upon the consumption, and the consumption is usually taken as a factor of the total daily displacement of the pump plungers. If a large percentage of the pumpage is waste, we can readily see that the works will be designed too large for the immediate needs of the community, and with a consequent expenditure of funds that in many cities can be ill afforded.

In the design, then, of new equipment, and, subsequently, if the station is to be operated on an efficient and economical basis, and the supply conserved, all unnecessary pumping should be eliminated.

The causes of this unnecessary pumping or water waste can usually be grouped under five heads: Pump slip, underground leakage, defective plumbing, carelessness, or wilful waste and surreptitious connections.

With pumps of the direct acting or non-flywheel type, there is frequent complaint that the pumps pound, and several arrangements have been supplied to produce more of a cushion at the end of the stroke. This cushioning has the effect of shortening the stroke and, of course, thus reducing the volume of pumpage. The pump counter, however, goes on counting the number of revolutions, and the daily report card shows so many revolutions at full capacity as the volume of water pumped.

Pump slip is not, properly speaking, a water waste, but is rather a waste of pumping effort, and should be kept as low as is practical. Just where this practical limit is we do not know exactly, but undoubtedly the same limit would not apply to all cities or to all types of pumps. About all we can say is that the practical limit is the point where the value of the water gained through close-fitting plunger and valves would be less than the value of the additional power required to overcome the added friction due to the tight packing. However, an allowable slip of 3 to 5 per cent. does not seem to be out of line with good operation and practice.

The detection of underground leakage is a very different matter than that of discovering and measuring pump slip. The distribution mains are covered up and we can only guess at what has taken place by a detail study of the pumping chart. The demand or consumption for a few hours after midnight, say, from 12 to 4 o'clock, is frequently indicative of the tightness of the system. At this time of the day the consumption is, or should be, at its minimum, while if the relative demand is high it is an indication that something is wrong.

There is always some leakage from the mains that cannot be checked, and it is usual to allow a loss of 2,000 gals.

per minute of 12-inch pipe, while for sizes other than 12 inches, the allowable loss is taken in the same proportion as the ratio of the diameters. One drop a second is not much of a leakage, and yet one drop a second from every joint in a mile of pipe would amount to approximately 1,400 gals. in 24 hours.

When the volume of consumption is abnormally high, there is reason to suspect that there are are unaccounted for losses, and the best way to satisfy oneself on the matter is to have a water waste survey made.

As an instance of what such a survey may accomplish, I wish to cite the results obtained in a city of some 3,500 people, in which the waterworks is owned by a private corporation. For some years the pumpage had been excessively large. Repeated appears to the consumers to be more careful brought no apparent relief, and finally an additional source of supply was developed entailing an expenditure of $10,000. This increased the available amount of water, but the volume of the pumpage in no way diminished, but rather increased. During April and the early part of May of last year the average daily pumpage varied from 680,000 to 700,000 gals. per 24 hours. A water waste survey located a blown-out lead joint in an 8-inch main wasting more than 300,000 gals. per day. This leak occurred under a broken stone-filled roadway, and behind a stone arch bridge at a point where the pipe was 14 feet below the street surface. The water was finding a ready outlet into the creek. Had this waste been discovered and stopped prior to the development of the new supply, the company would have been $10,000 better off in cash, and would have felt much easier in regard to the adequacy of their supply.

Another instance is a city of 2,000 population. The city operates a motor-driven 400,000-gal. triplex pump. From October, 1911, to June, 1912, it was necessary to operate the pump practically all the time to keep up the pressure, and even at that it seemed impossible to fill a 100-ft. standpipe more than half full. A water waste survey was made and a 4-inch pipe was found cracked squarely in two, permitting a leakage of 200,000 gals. per day, which found a ready outlet in an abandoned 12-inch tile storm water sewer, which crossed directly over the crack about 8 inches above the water main. There was no indication at the street surface of any such leak, though the pipe was laid but 4 feet deep, in fact the ground was not wet 2 feet away from the break. Incidentally I might add that the pump slippage was 25 per cent., leaving a consumption of about 100,000 gals. or 50 gals. per capita per day.

The method of making these surveys was substantially the same in both cases. At a point near the standpipe, an opening was made in the ground down to the main, and a 1-inch corporation tap was placed in the pipe in the usual way. A pitometer, which is a portable recording meter, was set up at this point, and a measurement of the flow during the night when the station was shut down was made. The city was then divided off into a number of districts, and during the day all the valves on the boundary line of the districts were closed, except one, which was left open to supply water to the district. That night after one o'clock this last valve in each district was closed, and the time when the valve went down was recorded. The rule was to begin at the outlying district and work toward the instrument. As each district was closed off from the supply the valves between it and the foregoing district were opened, so that when the night work was finished all the valves would be left open.

A comparison of the time each district was closed down, with the chart from the instrument, disclosed the district in which the loss occurred, for the minute the valve went down, which cut off the leak, the instrument recorded a drop in the rate of flow from the standpipe.

With the location of the loss in any particular district, it is generally a comparatively simple matter to locate the point of leakage by using an Aquaphone on the fire hydrants and sill cocks of the residences. Sometimes, however, the final location of the leakage is not so simple, and it is necessary to make a subdivision of the district, in this way usually the suspected territory may be reduced to a few blocks at the most.

The subdivision of a district into its smallest units is usually the method required when the losses are from defective plumbing, and in addition it is necessary to make a house to house inspection of the entire plumbing in each building. Carelessness in making proper plumbing repairs seems to be more prevalent in cities where the water is sold at a flat rate, the installation of meters having a wholesome effect on this class of consumers.

Carelessness as to fixture waste and wilful or deliberate waste are like defective plumbing, confined largely to the systems supplying water at flat rates. The sentiment seems to exist that so long as one is paying so much, what is the use of being careful, "We are entitled to all we can get out of the fixtures." This sentiment really reacts against the consumers, for with everyone in the same frame of mind the system becomes virtually a sieve, and of course the pressure is always low, especially in territory some distance from the pumping station. It all comes home to him in case of fire and no pressure.

Where such conditions exist it is sometimes a tedious task to locate and correct such losses, and the only way it can be done successfully is by a minute subdivision of the district, and night tests in the curb cock, together with daylight inspection of the individual premises. The returns in the value of the water saved usually far exceed the cost of doing the work.

Surreptitious or uncharted connections may occur almost anywhere, though they seem to be more frequent in the manufacturing districts of the larger cities. The making of a connection to a city water main by a private person or corporation is, of course, a deliberate intent to get something for nothing. Very frequently such connections are made from the fire service lines, which are extended into the grounds of the individual or company.

Where a survey indicates that there are surreptitious connections, the only way of definitely locating them is to segregate the suspected plant and measure the total amount of water going into the same. This, together with a very careful inspection of the fire lines and legitimate services, will usually produce a solution of the problem. It is needless to mention, however, that such work must be quietly and carefully done that correct results may be obtained.

It is a very unpleasant charge to make, but nevertheless it is true that in many of our cities and villages no record is kept of the location of the house service, and when the top of the curb box gets broken off or covered up, the service is "lost," and in case of repair or an order to shut off the service much time is lost in looking for the old box. In such cases the exact location of the service pipe can be quickly located by the use of a small electrical instrument called "A wireless pipe finder," and with the line of the service located in the ground, the shut-off box can be quite easily located by the use of a miner's compass, or as it is frequently called, a dip needle.

The latter instrument also comes in quite handy in locating street valves on the mains in unpaved streets where the boxes have been covered up by a road grader in crowning or shaping the surface of the street.

EXPERT EVIDENCE.

A strong opposition to the present metho[illegible]ing expert evidence in cases at law, and a [illegible] feeling that expert witnesses should be desig[illegible] the Courts, led the American Institute of Co[illegible] Engineers to hold a discussion on this most import[illegible] subject a short time ago.

The discussion brought out many interesting facts and viewpoints which have a direct bearing on existing conditions in this country. The present custom here, as in the United States, is for each side in a controversy to employ its own expert witnesses, just as it employs other witnesses, and the experts are examined and cross-examined in the same manner as ordinary witnesses. After summing up the opinions offered and in closing the discussion the chairman referred to a class of questions that require expert testimony, which can only be furnished by professional engineers, such as the valuation of public utilities, conflicting claims of water power companies, and the like. In such cases he felt time would be saved and the cases would be better presented if studied from ex parte points of view before the action at law is begun. The appointment of engineer associates by the court would probably be helpful in clearing up conflicting and confusing testimony.

Throughout the discussion a number of the speakers spoke of the importance of effecting a reform in expert practice by insistence on a higher standard of professional etiquette. It is doubtful if this would be a sufficient remedy. Better conditions can only be brought about by joint action of the engineering and legal professions.

STREAM AND RIVER IMPROVEMENT.

The necessity for the proper conservation of the water resources of the Dominion, and their utilization for the maximum benefit of the public has often been emphasized in these columns. We are prone, however, to neglect the placing of the necessary safeguards until it is too late, or until force of circumstances compels action.

Coal consumption is advancing at a rapid pace, so rapid, in fact, that complete depletion of the present available supply is only a matter of a very few years. We have not the figures to hand for Canada, but in the United States, in 1890, 2.54 tons of coal per capita were used, or a total of about 158,000,000 tons; in 1912, 5.73 tons per capita were used, or a total of 550,000,000 tons. It is certain that the increasing per capita consumption and the increasing population will deplete the supply at a much higher rate. The logical outcome will be that in a very short time, probably less than twenty-five years, the United States will prohibit the export of coal.

As Ontario has no coal resources of her own necessity will force the development of many of our water powers, which are today either too far from the market for commercial development, or too costly for economic use.

Water power development on a large scale is a product of recent years, and attention has often been called to this fact as the reason for its subservience to older institutions. We have grown firmly fixed in the habit of considering our streams as intended primarily for navigation, and are, therefore, prone to overlook the fact that in some cases a stream may have a higher utility as a source of municipal water supply or for irrigation or for power.

The ever-increasing demand for electric power must be met by the increased development of hydro-electric projects of greater capital cost. Water storage will be a necessary adjunct to many of these developments, and the public will then properly appreciate the value and importance of gauging records.

In a recent issue of Conservation, in referring to the dangers of over-estimation of available power, the following pertinent remarks are made: that engineers consider the problem simpler and easier than it really is; that they have not the necessary data, and that, lacking these, they have failed to acquire properly experienced judgment in such matters. This only emphasizes the need of governmental aid in providing adequate funds for the securing of continuous records of stream flow.

It is important to remember that streams can be put to many uses. The interests of navigation should only be given their proper weight in the matter of river improvement. Water-power development, municipal water supply, irrigation supply, the reclamation and protection of flooded lands, and the other incidental uses of water must receive due attention if the maximum utility to the public is to be secured.

EDITORIAL COMMENT.

In a recent paper before the American Institution of Electrical Engineers Mr. Esheleman remarks that when winding coils for electric machinery he found he could only earn $1.10 on the night shift, while on the day shift he earned quite $2. Moreover, while only 5 per cent. of the coils wound in the day time failed to pass the insulation test, as many as 10-15 per cent. of those done at night were rejected. This is quoted as an example of the disastrous effect of imperfect artificial illumination on the speed and quality of work.

* * * *

Testifying recently before the Commons Committee on pollution of streams, Dr. C. A. Hodgetts, chief medical health officer of the Conservation Commission, declared in favor of a Federal department of health with wide powers. He said: "Health Acts in Canada are nice to look at, but are not enforced," he said. "Municipalities do what they please, and there is no central power to say "You must do this." There is nothing in the B.N.A. Act which relegates public health control to the province." Dr. Connell, of Kingston, said that cities such as Montreal, Ottawa, and Toronto polluted their own water supplies with sewage, and that every city should be compelled to treat its sewage. He considered the St. Lawrence was polluted for sixty to eighty miles below Montreal.

* * * *

The idea of electrifying the railways seems to have got a firm hold of the public mind in Sweden, and much progress towards carrying it into execution has been made already. The first great step is the electrification of the Kiiruna Railway from Kiiruna to the Norwegian frontier. This work has been advanced rapidly of late. A start has been made with the building of the transformer stations, and it is anticipated that the whole line will be opened for regular traffic in the course of this year. Satisfactory progress has also been made with the line between Stockholm and Saltsjöbaden, which is also to be completed this year. The State Railways besides have made extensive experiments with two Diesel electrical locomotives, which have given very satisfactory results, while five private lines have had the question of electrification examined by experts for the working out of estimates as to the cost, etc.

* * * *

A steamer intended for the Hydrographic Service of the Canadian Government was launched from the Neptune Works of Swan, Hunter & Wigham Richardson, Limited, on Thursday, the 8th inst. The vessel is 170 feet in length by 33½ feet beam, and will be built to attain the highest class in Lloyds' Register. She will be propelled by a set of triple expansion engines, supplied with steam by two boilers working under Howden's forced draught, both engines and boilers being constructed at the Neptune Works, and expected to drive the vessel at 12 knots per hour. The steamer will be schooner rigged. She is built of steel, and strengthened to enable her to run through ice, and will be completely outfitted for her intended service, having two motor launches, Lucas sounding machine, marine sentry, sounding winch, electric light, with projector, etc. Besides the usual accommodation for the deck and engine-room officers, there will be well-furnished rooms for the various officials engaged in survey work. The vessel is being constructed to the designs and under the superintendence of Mr. R. L. Newman, of Canada, whose representative in England is Mr. F. L. Warren, of London, and both Mr. Newman and Mr. Warren were present at the launch. As the steamer left the ways she was named the "Acadia," the naming ceremony being gracefully performed by Miss Hilda Thompson, daughter of Mr. R. Thompson, consulting engineer, of London.

THE WATERWORKS AND SEWAGE SYSTEMS OF CANADA.

Some few years ago *The Canadian Engineer* published a table showing the water consumption in various cities throughout Canada, together with other data covering the plants then in existence, which table attracted a good deal of attention at the time it was published.

TABLE I

NUMBER OF WATER-WORKS PLANTS IN EACH PROVINCE, CLASSIFIED ACCORDING TO SOURCE OF SUPPLY, MODE OF SUPPLY, POWER USED, ETC.

Province	No. of Plants Supplied From			No. of Plants Using Filters	Mode of Supply		Kind of Power Used					Ownership		Rates on Which Charges Are Made		
	Springs or Wells	Lake	River		Gravity	Pumped	Water-Power	Steam	Electricity	Gas	Gasoline	Municipal	Private	Flat	Meter	Both F. and M.
Nova Scotia	13	12	4	1	19	10	1	9	—	—	—	25	4	18	—	10
New Brunswick	13	1	2	1	7	9	—	6	1	2	—	14	2	11	—	4
P.E. Island	3	—	—	—	1	2	—	2	—	—	—	2	1	—	—	2
Quebec	42	11	41	15	48	46	8	24	11	1	2	57	37	31	—	3
Ontario	69	28	47	19	18	126	21	66	24	7	6	125	19	75	5	55
Manitoba	4	—	4	2	—	8	—	6	—	1	1	8	—	3	3	—

Table I.

In this connection engineers will, however, be pleased to learn that the Commission of Conservation undertook, some little time ago, to compile statistics covering this phase of engineering in Canada. As a result of their labors they have issued a book which contains a number of very interesting facts, and we are pleased, therefore, to be able to reprint the accompanying tables, taken from the report, which we are sure will be read with a good deal of interest by municipal engineers throughout the country.

The tables are self-explanatory. It is interesting to note the accompanying curve as showing the increase in the number of waterworks plants since 1850. From 1850 to 1875 the development was not very rapid. From 1875 to 1890 the development was much more rapid, and it will be seen that since 1890 to 1910 the development has been fairly constant; whereas in 1880 there were about fifty plants, in 1910 there were something like three hundred and sixty in operation.

TABLE II

NUMBER OF WATER-WORKS PLANTS IN CANADA AT THE BEGINNING OF EACH FIVE YEAR PERIOD, 1850-1911

Province	1850	1855	1860	1865	1870	1875	1880	1885	1890	1895	1900	1905	1911
Nova Scotia	1	1	1	1	2	3	3	5	11	20	24	29	29

Table II.

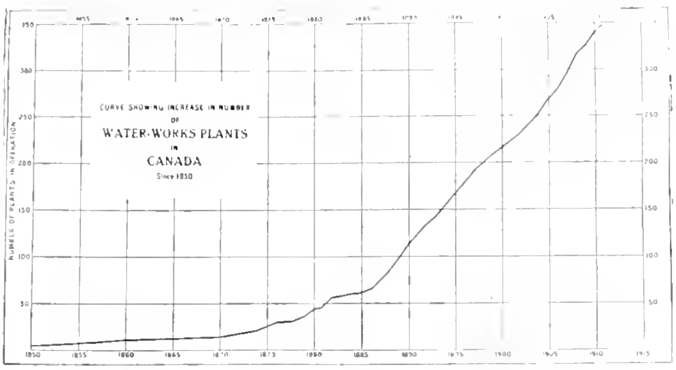
SUMMARY TABLE

TOTAL COST OF PLANTS, CONSUMPTION, MAINTENANCE CHARGES, ETC., FOR THE DIFFERENT PROVINCES

(In this compilation, the items which it was impossible to obtain from the municipalities, have been estimated)

Province	Cost of Plants (dollars)	Total Daily Consumption (imp. gal.)	Annual Maintenance, exclusive of interest (dollars)	Total Length of Mains (miles)	Estimated cost per 1,000 gal.* (cents)	Estimated cost per Capita per year* (dollars)	Daily Consumption per Capita (imp. gal.)
Nova Scotia	4,534,682	21,436,662	176,602	393	7	3.76	147
Pr. Edward Is.	365,506	802,000	11,543	29	16.4	2.87	48
New Brunswick	3,563,939	15,278,500	101,616	186	8.2	4.82	161
Quebec	31,224,883	110,800,000	731,694	1,157	9.5	3.92	113
Ontario	37,813,117	151,203,363	1,601,077	2,182	9.6	4.21	120
Manitoba	4,852,868	9,791,213	251,141	297	20.6	3.40	46
Saskatchewan	2,461,810	4,480,000	131,202	156	23	3.88	46
Alberta	4,485,802	14,685,000	248,589	313	13	6.27	132
British Columbia	6,263,769	26,997,000	181,735	502	8.2	3.44	115
Canada	95,566,496	360,477,638	3,435,199	5,215	10	4.12	113

* These costs are approximate only, and have been calculated from the annual maintenance costs, plus an allowance of 10 per cent. of the cost of plants for interest and for depreciation.



Tables I. and II., together with the summarized table, reveal a number of interesting comparative facts. This interesting and valuable report was prepared by Leo G. Denis, C.E.

Plans for Victoria harbor improvements progress steadily. This year will see the large docks well under way. These are to be built by Sir John Jackson & Company, and something will be accomplished also in connection with the dredging of False Creek in Vancouver. To give better facilities for shipping, it is announced that the government will establish a drydock at Esquimalt, this being stated as part of the naval scheme on the Pacific. Mayor Baxter, of Vancouver, who was in Vancouver in connection with harbor and other matters, returned on the 1st instant, and reports that it is very probable that a drydock will be built at Vancouver along the lines of some of the schemes proposed heretofore.

WATERPROOFING CONCRETE.

To make cement and concrete impervious to water a number of waterproofing materials have been devised, such as "Medusa," sold by Stinson-Reeb Builders' Supply Company, of Montreal; "Pudlo," sold by W. H. Thornhill & Company, of Winnipeg; "J. M.," sold by the Canadian H. W. Johns-Manville Company, Limited; and the "Kahn Paste," sold by the Trussed Concrete Steel Company, of Canada, Limited, etc. The benefit derived from waterproofings of this nature, where resistance to water or dampness is desired, has been well established, and it may, therefore, be of interest to review briefly a few of the claims made by the various manufacturers.

Mr. Kennedy Stinson states that "Medusa" waterproofing does not affect the color, strength, setting or hardening qualities of concrete, and when used in the proper proportions it will make any concrete work impervious to water and prevents discoloration from rain. It prevents the white efflorescence which so often makes cement work unsightly, and also prevents the appearance of hair cracks on the surface. It has been shown by LeChatelier that the destruction of concrete by sea water is due to the diffusion of the sulphates of the water through the mass and the action of these salts on the constituents of the cement.

There is good reason to believe that "Medusa" waterproofing, by preventing this diffusion, will enable concrete to resist perfectly the injurious action of sea water. Mr. Stinson says that by the use of "Medusa," waterproofing qualities will be obtained which could otherwise be secured only by the use of very rich and expensive mixtures. "Medusa" is a dry, white powder consisting of fatty acids chemically combined with lime. It is thoroughly mixed dry with dry cement before the sand and water are added.

The name "Pudlo" is coined from "puddle," which, according to the dictionary, means "to make watertight by means of clay." "There is great loss of labor and loss of space when clay puddle is used for reservoirs, ponds, tanks, etc.," says Mr. Thornhill, "and Pudloed cement means quicker, easier and cheaper work, with all leakages avoided." "Pudlo" is a fine, white powder, which should be mixed with neat cement in varying proportions, according to the purpose for which it is required. It is said to prevent all leakages, making cellars and basements damp resistant, even when built alongside the water's edge. It prevents dampness rising in concrete floors and makes reinforced concrete absolutely dampproof.

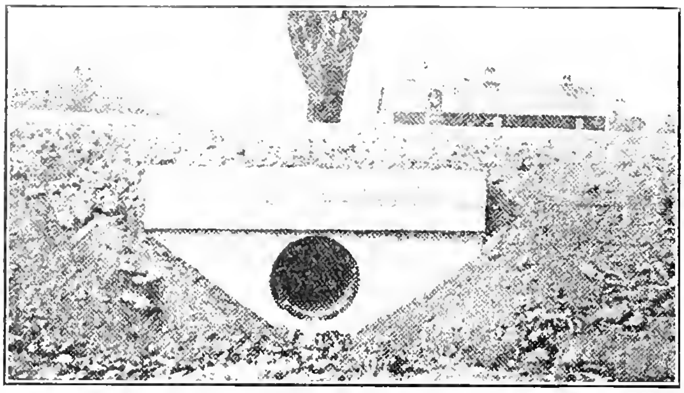
It allows flat roofing to be done in cement. It is said that "Pudlo" completely fills the voids in cement and cement mortar, and slightly increases the strength of same. The manufacture of "Pudlo" is based upon an earthy fat of such a nature that it enters into chemical amalgamation with cementitious substances. A chemical action is set up in the cement, owing to the silica in the cement being absorbed or dissolved by "Pudlo." The presence of hard silica in cement makes it porous. When the silica is dissolved the cement has no crevices left in it and percolation cannot occur. Mr. Thornhill especially calls attention to the advisability of "Pudlo" for sewers, which should certainly be airproof and odor-proof. "Pudlo" will prevent hair cracks and efflorescence on cement work.

The Canadian H. W. Johns-Manville Company state that their "J. M." waterproofings are made of non-organic materials, and are practically everlasting. Their waterproofings have been used for basements, bridges, reservoirs, abutments, mastic floors, etc.

The "Kahn" waterproofings are in the form of a paste, which is dissolved in the water from which the concrete is made. Both paste and powder waterproofings are easily shipped and do not evaporate, so they have a certain amount of advantage in that regard over liquid waterproofings.

CONCRETE CULVERTS FOR COUNTRY ROADS.

In a recent bulletin issued by the North Carolina Geological and Economical Survey there is to be found much valuable information pertaining to the design and construction of concrete waterways for country roads. The bulletin is entitled "Culverts and Small Bridges for Country Roads in North Carolina," by C. R. Thomas, Highway Engineer, U.S. Office of Public Roads, and T. F. Hickerson, Highway Engineer of North Carolina.



Concrete End Wall for Pipe Culvert.

Some of the culverts have been built with Merillat collapsible cores and metal forms have been used by the highway department successfully in the construction of small bridges. The bulletin is in the nature of a textbook of waterways for highway builders, and its treatment of the concrete structure is plain, comprehensive and authoritative.

The following extracts are taken from the bulletin:

Concrete is a properly proportioned mixture of cement, sand and stone, which when mixed with water forms an artificial stone. It is called plain or reinforced depending on whether steel is used to give it additional strength.

Concrete culverts and bridges possess the following merits:

(1) Permanent; (2) Can be built with inexperienced labor; (3) Require no repairs; (4) Materials are readily obtained. On the other hand they must be properly designed and carefully built to be satisfactory.

Concrete Waterways.—Plain and reinforced concrete may be used in all shapes of waterways which usually occur on country roads. The shape to use, whether a pipe, box, slab or arch will usually depend on the location of the structure.

Staking Out: In laying out a waterway the length should first be determined. This is largely a matter of personal choice, but as a general rule structures having 25 square feet area of waterway or less should extend completely across the graded width, no guard rail being necessary; and those having over 25 square feet area of waterway should not be less than 15 feet long, preferably 20 feet.

The foundations are laid out according to the dimensions of the plans. A small stake is placed at each corner and a light cord is stretched between the stakes to serve as a guide in excavating the earth. The character of the soil sometimes makes it necessary to excavate beyond the width required for the concrete. The earth bottom should be trued with a straight edge and level. If footings are used, small stakes may be placed on the sides of the trench with their tops level with the top of the footing and the concrete brought up to them. It is important that the top of the footing should be true, as it is difficult to set the forms on any uneven surface.

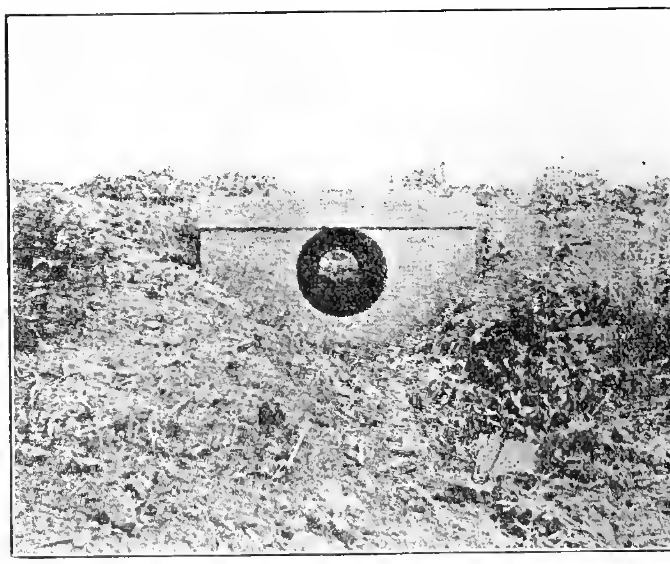
A tape, straight edge, and good carpenter's level are usually all the tools necessary to do the staking out. It is convenient to remember that the sides of a right triangle are in the ratio 3:4:5. For example, when the zero and 12 ft. marks on the tape are held together, and the 3 ft. and 7 ft. marks held along a wall the zero is perpendicular to the wall.

Except in waterways requiring a guard rail it is neither necessary nor advisable that the tops of both parapet walls be at the same elevation.

Methods of Design: All the culverts and bridges illustrated in this bulletin are designed to support a 15-ton road roller. 1:2:4 concrete is used for all slabs, beams, parapet walls, and reinforced bottoms. 1:2½:5 concrete is used in side walls and foundations. The concrete in beams and slabs is designed to be stressed to 700 pounds per square inch. The reinforcing steel is computed for plain square bars of mild steel with an allowable stress of 16,000 pounds per square inch. Round, twisted, or deformed bars may be used in place of these, provided the cross-sectional area of steel remains the same.

Pipe Culverts: Several designs for solid concrete pipe are shown. In building these a collapsible metal form similar to the one illustrated in Plate IV. has been found very convenient.

The form for the half-round culvert should be made of No. 10 gauge sheet metal with a 1½ x 1½-inch angle riveted on the edges, rods with turnbuckles 4 feet apart serving to spring the form. A beveled 2 x 4-inch wooden strip must be placed under each edge in order to strike the form. A piece of No. 10 gauge sheet metal cut to fit the top of the form will serve for an end wall form.



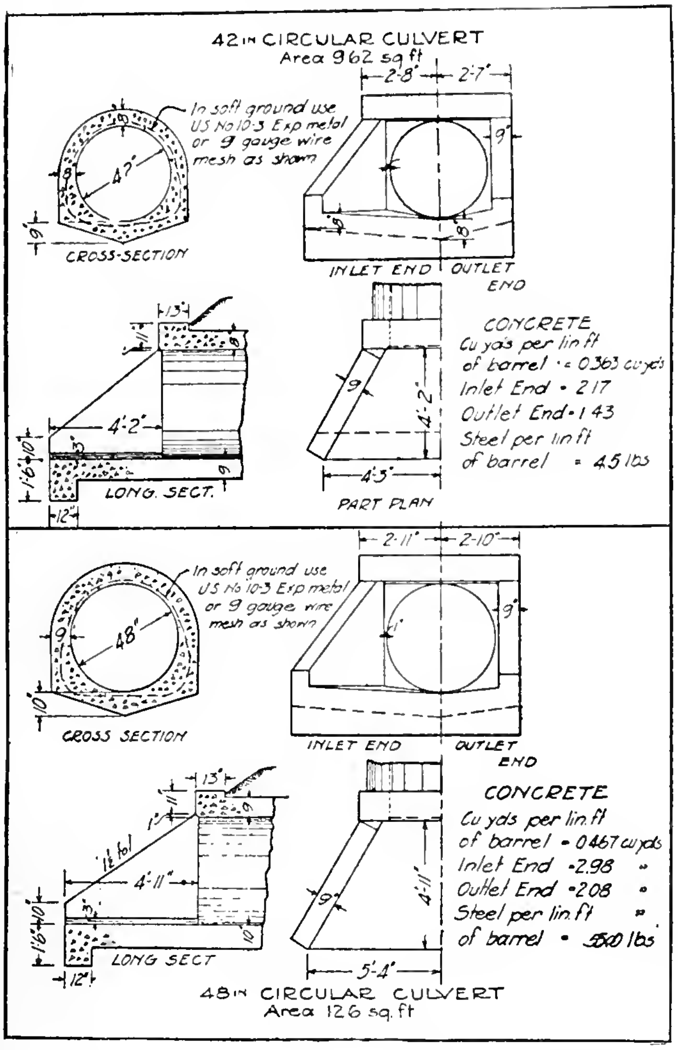
Culvert Made With Collapsible Form.

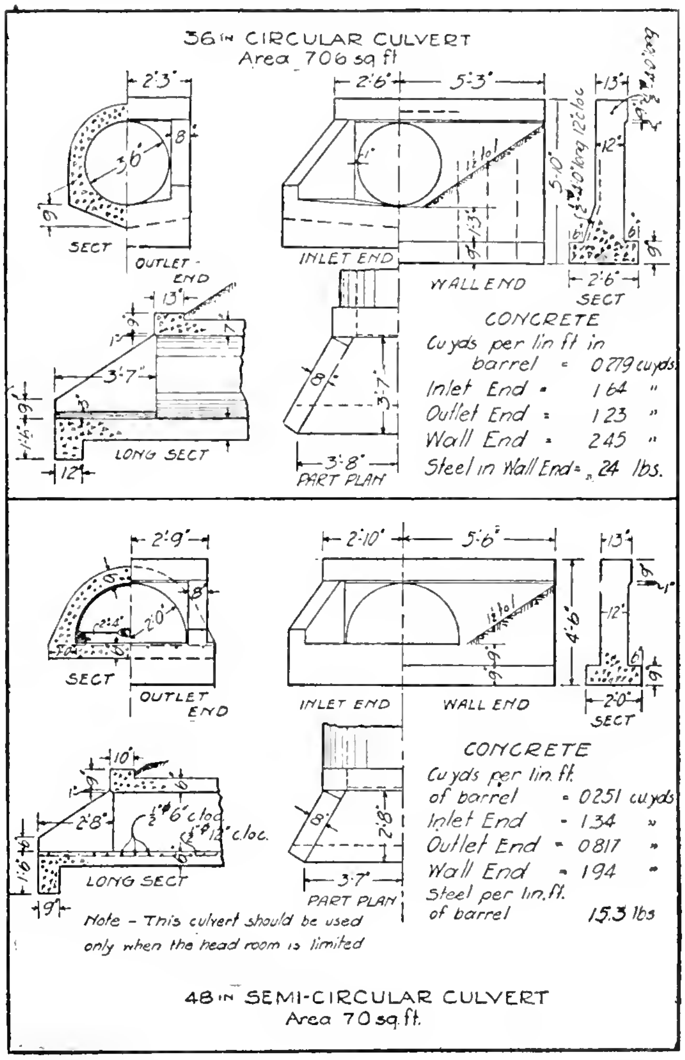
In building these culverts the bottom is put in level and allowed to set, being careful to have it true from end to end. The form is then placed and the concrete deposited for the length of the section. After 24 hours the form may be withdrawn and set for the next section of the pipe. Ordinarily no wooden forms are necessary except for the end walls.

Box Culverts: Plates VIII. and XI. are photographs of various types of end-walls for box culverts. Expanded metal or triangular wire mesh reinforcement may be used in place

of the rods. These culverts are provided with baffle walls which in some cases, may be omitted at the upper end. At the lower end it may sometimes be necessary to increase the depth of the baffle wall or to place a baffle wall under the wings as well as at the end. In striking the inside forms the joists supporting the top of the culvert are knocked out, the top forms drop down and the side forms spring in. It is often possible to excavate the trench to the exact size and shape of the culvert, doing away with outside forms. However, the side walls must be thicker when this is done.

Guard Rails: Either pipe or solid concrete rails may be used on the concrete structures described. Pipe guard rails are cheap, sightly and on the whole, satisfactory, although they require some maintenance. They may be supported while the concrete is being placed, as shown in Fig. 11.





They should be given a thin coat of red lead and oil, followed by two good coats of white lead and oil after the bridge is completed. Pipe railing will cost about $0.50 per linear foot of single rail.

Concrete rails are very sightly but are difficult to construct and very expensive and are not recommended for ordinary country work.

Cost of Concrete.—The cost of concrete in small structures on country roads will vary somewhat from its cost in town or on large jobs. A main point of difference is probably in the cost of materials delivered on the job. Another difference comes in the delay and expense of continually moving the plant from one point to another.

The cost of hauling material to the work [illegible] 30 cents per cubic yard for every mile it must be hauled. An ordinary wide tread, slat bottom wagon bed containing a cubic yard is 38 ins. x 8 ft. 6 ins. x 12 ins. in size, inside dimensions, and is usually as much as the average team can handle over bad roads. An inch added to the height of the side boards increases the capacity of the bed .083 cubic yard.

Loading sand or gravel into a wagon bed will cost from 7 cents to 10 cents per cubic yard where shovels are kept busy, but may cost as high as 15 cents when the driver loads his own wagon.

A small gang with four good men mixing and one man shoveling material into barrows and putting on water, should mix and wheel 40 or 50 feet from 8 to 10 batches or 6 to 8 cubic yards of 1:2½:5 concrete, assuming a batch contains one barrel (four bags) of cement. The cost of this mixing will vary from 80 cents to $1.15 per cubic yard.

On small jobs where new forms are required, the cost of framing and erecting the forms will never be less than $12 to $15 per 1,000 ft. B.M. of lumber used, due to the large amount of cutting and fitting necessary. On larger jobs the cost may be reduced to $8 to $10 per 1,000 ft. B.M. These costs are much less when old forms are used. Lumber will cost from $22.50 to $30 per 1,000 ft. B.M. Steel rods will cost from 1¾c. to 2¼c. per pound, delivered in most sections of the state.

The labor cost of bending and placing steel is about ½ cent per pound. This will be increased slightly if many rods greater than ¾ inch in diameter must be cut cold.

The cost of excavating for foundations will vary from 50 to 80 cents per cubic yard in dry earth and will generally vary between $1.50 and $3 per cubic yard where small puddle cofferdams not over 6 feet deep must be built.

Tearing down forms, finishing and cleaning up around the work will usually cost about 10 cents per cubic yard of concrete.

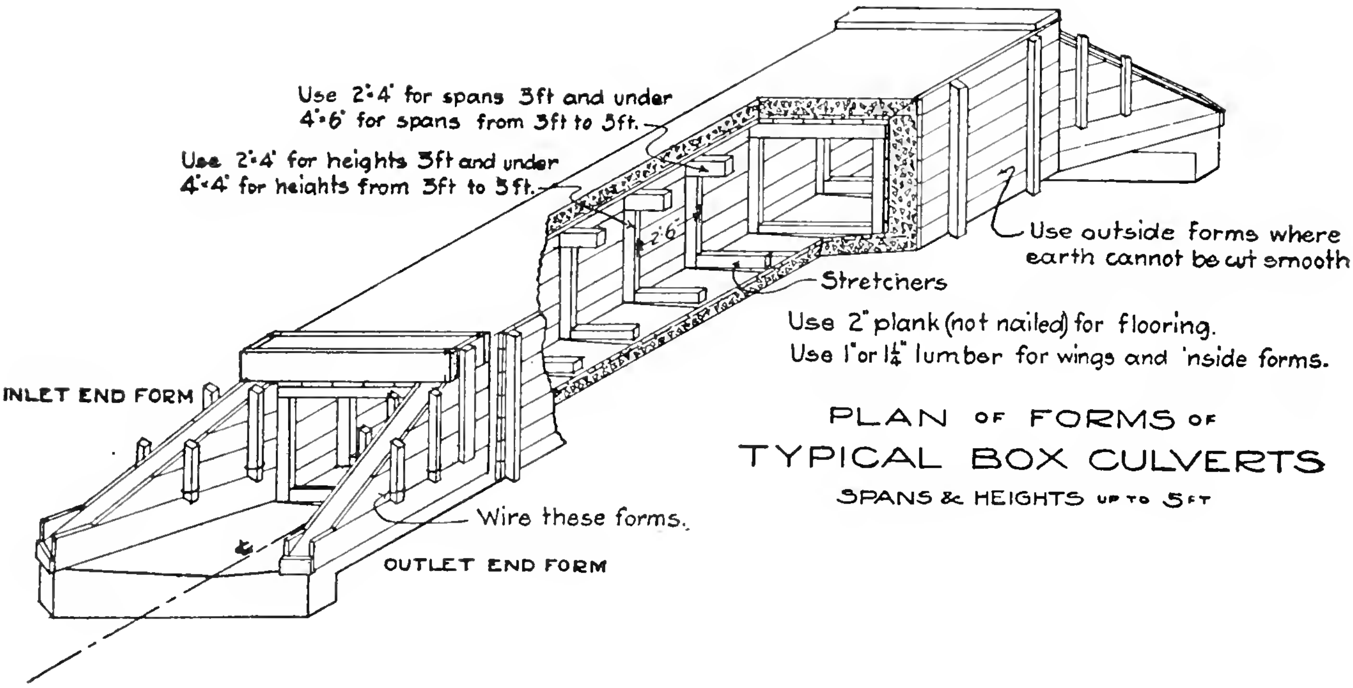
The cost of moving the plant from one job to another will usually be from $10 to $20, where the plant is not moved over five miles.

The cost data below is for a small 4 x 5 box culvert 26 feet long, built according to the designs in this bulletin and illustrated in Plate VIII.

The work was done by a regular county concrete gang, composed of a foreman seven men and two teams with drivers, and was completed in four days of 10 hours each. The excavation was light, but the soil was of a hard, black nature that was hard trimming. Water for mixing had to be hauled two miles.

Material (laid down at culvert).

Cement, 26 bbls. at $1.80	$ 46.80
Hauling cement, 12½ hrs. at 30c.	3.75
Gravel, 18½ cu. yds. at $1.10 f.o.b. cars Ennis, Texas	20.35
Hauling, 18½ cu. yds., 46 hrs., at 30c. (75c. per cu. yd.)	13.80
Steel, 1,072 lbs. at 2½c.	26.80
Hauling steel, 2 hrs. at 30c.	.60
Lumber, 1,000 ft. B.M. at $25	25.00
Hauling lumber, 3 hrs. at 30c.	.90
	$138.00
75% salvage on form lumber	18.75
Total cost of material at job	$119.25
Total cost of job	$180.45



PLAN OF FORMS OF
TYPICAL BOX CULVERTS
SPANS & HEIGHTS UP TO 5 FT

Sand gravel was used for aggregate in the concrete. The gravel contained a slight excess of sand and worked up in proportions given. Mixing was done by hand with negro labor. Twisted square steel bars were used for reinforcing.

Labor.

Foreman, 40 hrs. at 25c.	$10.00
Culvert excavation, 9 cu. yds. at 80c.	7.20
Labor on forms	14.00
Mixing and placing, 120 hrs. at 15c.	18.00
Hauling water, 20 hrs. at 30c.	6.00
Cutting and placing steel, 10 hrs. at 15c.	1.50
Cleaning up and removing forms, 10 hrs. at 15c.	1.50
	$58.20
50% salvage on form lumber	7.00
	$51.20
Moving on and off job	10.00
Total labor at culvert	$61.20

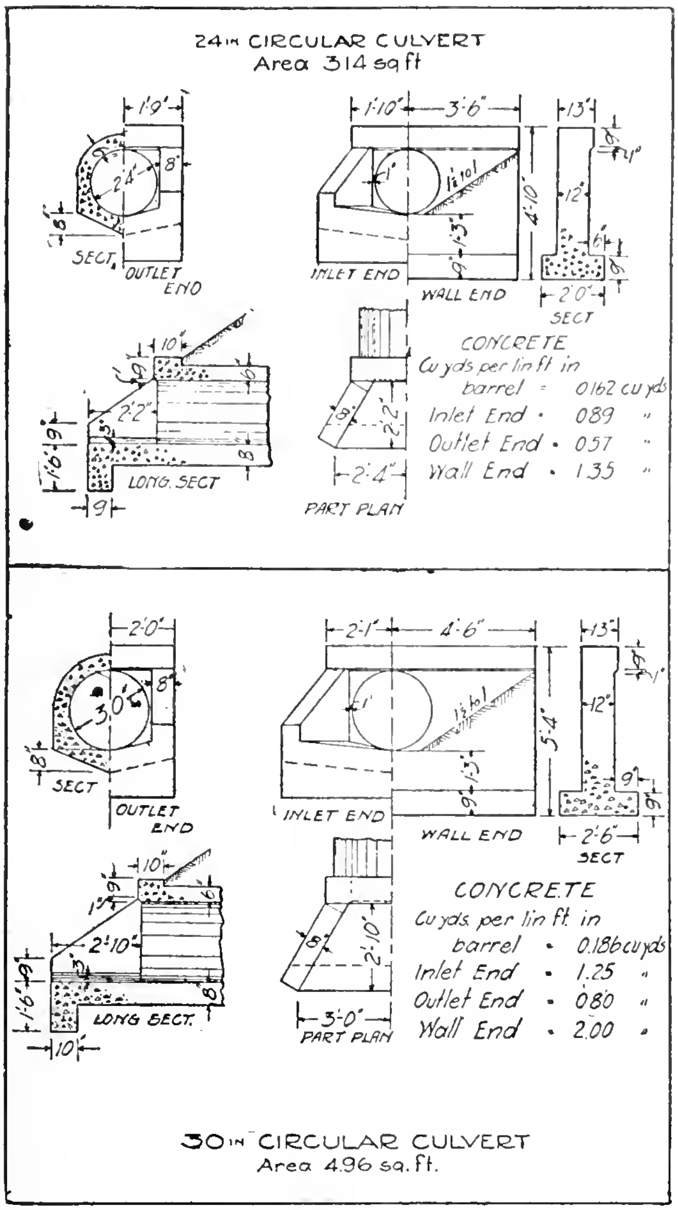
Cost per cu. yd. of concrete in place exclusive of culvert excavation	$ 9.37
Cost per cu. yd. of concrete in place exclusive of excavation and steel	7.85

The quantities were as follows: 14½ cu. yds. of 1:3:5 concrete; 4 cu. yds. of 1:2½:4 concrete; 432 lbs of ¾ in. steel; 640 lbs. of ½ in. steel; and 1,000 ft. B.M. of lumber.

In estimating the cost of work it is well to use a form similar to that shown for the cost data above. When it is desired to find the probable cost per cubic yard of concrete, Table VII. is convenient. The various amounts of each material are determined and multiplied by their cost per cubic yard laid down at the job, these costs varying for almost every case. The other costs which are more nearly constant may then be added as shown below.

For example, if 30 cu. yds. of 1:2½:5 concrete is needed and the cost of material laid down at the job is as given, its cost per cubic yard may be approximately estimated as follows:

Cement, 1.37 bbls. at $1.50		$2.06
Sand, 0.48 cu. yd. at $0.50		.24
Stone, 0.96 cu. yd. at $0.50 to $1.50	$0.50 to	1.45
Mixing and placing		1.00
Forms (labor and material)	.50 to	.75
Hauling material	.50 to	3.00
Foreman, moving, cleaning up, etc.		1.00
Plain concrete (per cubic yard)	$5.85 to	$9.50
Reinforcing steel (0.5% to 0.8%), 66 to 106 pounds at 3c. per pound in place	2.00 to	3.20
Reinforced concrete per cubic yard	$7.85 to	$12.70



It will be seen that the cost of hauling and the cost of stone or gravel will greatly influence the cost of the concrete.

Westinghouse, Church, Kerr and Company, are now in their new offices at Wall Street, New York City.

An issue of *The Canadian Engineer* for March the 28th, 1912, is desired. Subscriber sending in same will have subscription extended one month.

CONSTRUCTION WORK IN REGINA.

(Staff Correspondence.)

The much-talked-of money stringency does not [illegible] to have had any great effect on building operations in Regina. Arrangements are being made for the early construction of the proposed new power house which will be situated on the banks of the Wascana Lake, and will cost about $425,000.

The library board is urging the city council to erect two new libraries—one in the northwest section of the city, and the other in the east end. So far the city council has looked with favor on the proposition.

The Parsons Construction Company have just completed the outside work on the Connaught School, and expect to have the remainder of the work finished in time for the occupation of the school by September 1, the commencement of the fall term. This school will contain 22 rooms and will contain equipment for manual training and domestic science in addition to the regular class-rooms.

The Regina College will erect this year: (a) Two towers on top of the present college building at a cost of $80,000; (b) a ladies' college and residence, funds for which have been provided for out of the Massey estate, at a cost of $100,000; (c) a boy's residence to cost $100,000.

The Anglican church also has an ambitious programme on hand, the most important of which is the St. Chad's College and Synod House. The college will be three stories and basement, and will be built of pressed brick and terra cotta trimmings, in the Gothic style of architecture. The main building of the college will be 175 feet by 60 feet. There will also be a chapel of the dimensions of 62 feet by 24 feet. The total cost will be about $100,000. The Synod House will be two stories and basement, built of the same material and same style of architecture as the college. The cost will be about $7,000.

It is expected that construction work will be commenced on the proposed new armories within the immediate future. The cost of the buildings is to be in the neighborhood of $250,000. There will be a full-sized basement and the area covered by the entire building will be 145 feet by 275 feet. The construction will be clinker brick. Arrangements will be made for a drill hall, club rooms, store rooms, bowling alleys, shooting galleries, officers' quarters, etc.

Architect Fortin is now busily engaged on the preparation of plans for the new Roman Catholic bishop's palace, which it is estimated will cost in the neighborhood of $50,000.

One of the best warehouses to be erected in Regina during the present year will be that of the British Columbia Sugar Refinery. The contract for the erection of this building has already been let. It will have ground dimensions of 150 feet by 113 feet, and will be of brick construction.

The house problem, which was a very vexatious one at the commencement of the spring season, has now been practically solved. The private firms doing business in the city have worked together well with this end in view, and the result has been that various firms have erected houses in groups varying from six to one hundred. The result has been that plenty of accommodation has now been made possible. The building of dwellings, however, continues to go steadily ahead, in order that the hundreds of newcomers who arrive weekly may be accommodated. Some of those who have taken out permits for houses, and the number of houses are named below: Seven houses on Montague Street for T. Davidson; five houses on Montague Street for Grant & Lounsborough; 20 houses in Lakeview; 34 houses in Eastview and Eastern Annex by J. K. McInnis & Sons; three

houses in Rosemont by G. W. Sloan; 20 houses in Parliament Heights by Fraser and Keenleyside. The houses being erected by Fraser and Keenleyside will cost from $4,000 to $6,000 each and will be for rent.

Many high-class dwellings will be erected in Lakeview sub-division this year. Messrs. McCallum, Hill & Company have sold considerable of the property fronting on Albert Street at $80 per foot frontage. The lots so sold have not had a frontage of less than 80 feet and in some instances 100 feet. It is stipulated that the purchaser in each case erect a dwelling to cost at least $8,000, work on which must commence within two months. McCallum, Hill & Company estimate that the total value of dwellings to be erected on the $27,000 of this property sold within the past four days is $85,000 at least.

Dr. Andrews has requested the city council to allow him to try his new style of paving which, according to his statement, costs only a fraction of the cost of ordinary pavement. Dr. Andrews only asks a royalty of one cent per square yard, above actual cost price. Arrangements have been made for Dr. Andrews to meet the civic works committee before the contracts for paving are let.

Mayor Martin has been instructed officially by M. Donaldson of the G.T.P. Railway Company, that the work of constructing the $1,000,000 hotel "The QuAppelle" will be commenced immediately, the contract having already been let.

Howell, Smith & Company have announced their intention of erecting 50 houses of from six to eight rooms each, in the C.P.R. annex, providing the city will agree to extend the sewer and water mains to serve the property.

Balfour, Broadfoot Company have also announced their intention of erecting a number of high-class dwellings in Belvedere. Work will likely be commenced on them within the course of the next week or two.

Fordyce & MacNeil have announced that they will erect a $25,000 apartment block in Parliament Heights.

The police commission of Regina has turned down the plans for the police station prepared by Architect Fulton, and which were accepted by last year's commission. Competitive plans are being called for. Architect Fulton will be paid, however, for his work.

CANADA'S CANAL TRAFFIC.

The total quantity of freight passed through the several divisions of the Canadian canal system during the season of 1912 is as follows:—

——	Farm Stock	Forest Produce of Wood	Manufactures	Products of Mines	Agricultural Products	Total
	Tons	Tons	Tons	Tons	Tons	Tons
Sault Ste. Marie.	372	54,114	975,303	34 109,074	4,530,792	39,669,655
Welland..	678	227,684	625,569	797,072	1,205,912	2,851,915
St. Lawrence......	9,375	578,760	464,091	1,305,395	1,119,567	3,477,188
Chambly..........	338	425,313	11,600	161,458	19,706	618,415
St. Peter's.......	2 996	11,161	7,583	37,642	15,427	74,809
Murray.	37	706	101,511	67,379	448	170,081
Ottawa.	2,880	226,600	20,958	136,634	5,278	392,350
Rideau.........	3,151	28,642	18,814	105,531	3,995	160,133
Trent.	361	67,489	3,459	3,327	2,514	77,150
St. Andrew's......	......	14,153	60	81,299	37	95,549

The total quantity of freight moved on the Welland Canal was 2,851,915 tons, of which 1,205,912 tons were agricultural products.

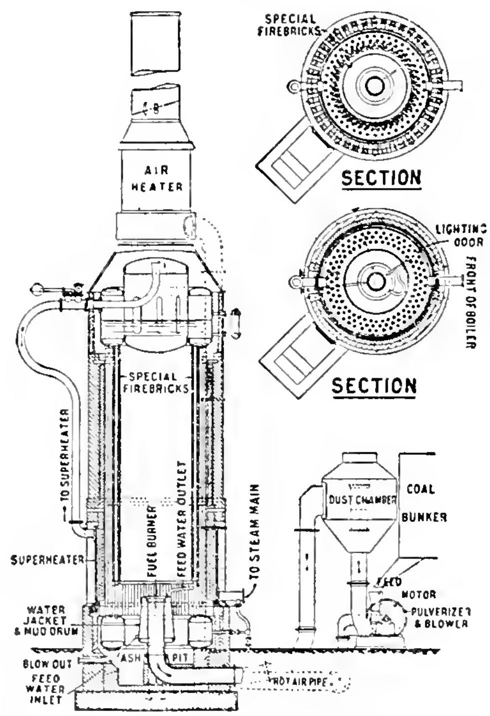
On the St. Lawrence canals the total quantity of freight moved was 3,477,188 tons, of which 1,119,567 were agricultural products, and 464,091 tons were manufactures.

On the Ottawa canals the total quantity of freight moved was 392,350 tons; of this quantity 226,600 tons were the produce of the forest.

THE BETTINGTON DUST-FUEL BOILER.

In these days, when the question of fuel occupies the minds of so many engineers and others interested in the generation and transmission of power, the following description of the Bettington boiler, gathered from a paper read by H. V. Hart before the Manchester Geological and Mining Society, will be of interest:—

It has long been known that an almost perfect combustion can be obtained by the introduction of finely pulverized coal, with a correct proportion of air, into a heated furnace. Attempts have been made in the past to burn dust by blowing it into the furnaces of Lancashire boilers, but it was found that the flues soon became filled up with partly consumed dust, and that the output of the boiler was consequently reduced. Other methods have been tried, but it has been found impossible to keep intact the brickwork with which the furnace is surrounded. Up to the present, therefore, the use of pulverized fuel was limited to the burning of cement in special kilns, no commercial success having been established in its use for firing boilers. A plant that has successfully overcome these difficulties has been erected at the Outwood Collieries, near Manchester, as herein described.



SECTIONAL VIEWS OF BETTINGTON BOILER

A complete system of dust collection has been installed A fan, 25 inches in diameter, running at 680 revolutions per minute, and driven by a 12 horse-power motor, produces the suction required, and delivers the coal dust into a large cyclone collector some 20 feet high and 10 feet in diameter. The air and dust enter the collector at the side, and, the air being made to revolve, the dust separates and descends by gravity to the bottom of the cone, while the air is expelled at the top. Galvanized iron pipes of suitable diameter for carrying the dust are led from the tipplers, screen, collecting-belt, railway waggons, and bunker; two sweep-ups are also provided at the ground level. The coal dust is drawn off the collectors into colliery tubs, and deposited by means of a creeper and a hoist into the bunkers of the dust-fuel boiler.

The Bettington boiler is the outcome of many experiments made in America and South Africa, and was designed primarily for burning low-grade fuels in those countries The boiler is constructed for a working pressure of 160

pounds per square inch, and to superheat the steam by 110 degrees Fahrenheit. It is of the vertical multitubular type, consisting of a bottom and a top heater, supported by three rows of tubes, 3¼ inches in diameter, and so designed that expansion can take place without straining the boiler, the air-heater and chimney being supported on brickwork independent of the boiler structure.

The boiler is fired by a central tuyere, or gas-jet, 14 inches in diameter. This tuyere is water-jacketed, and cooled by the feed-water, which is led by a special tube from the jacket to the top-header. The steam passes out from this top-header in a saturated state, and is led down to the superheater. The superheater is made up of a series of horizontal tubes which pass round the boiler, between the brickwork and the outer row of vertical tubes, the steam finally leaving the boiler at this level.

The fuel is led from the bunker, by means of a worm, into an electrically-driven pulverizer, running at 1,500 revolutions per minute. The pulverizer consists of a number of manganese-steel blades, or beaters, revolving in a casing lined with steel liners. These beaters grind up the coarser particles of coal, and constitute a fan which produces the necessary draught for forcing the dust into the furnace. Two slides are provided on each side of the casing for varying the amount of air required for combustion. Air is also drawn from the air-heater situated in the chimney stack, the coal-feed being regulated by a variable speed device fitted on the worm-shaft. The coal-dust is then forced, together with a correct proportion of air, into a separator; the fine dust is blown through a gauze, the larger particles falling down to be repulverized.

It is found that, owing to friction and expansion, the air soon loses its initial velocity, but that the particles of coaldust continue in their upward direction until they strike the top of the furnace, where, owing to gravity, and to the fact that they are cooled by striking the under side of the top-header, they descend, and, in exceeding the velocity of the air, become completely oxidized.

The size of the dust particles is, therefore, limited to that which can be completely consumed in the time occupied on the journey up and down the furnace; and it has been found in practice that this furnace will consume coarser particles of coal than any other which has hitherto been constructed for burning pulverized fuel.

The ash in the fuel, during its passage through the furnace, is converted into a liquid spray, the greater portion of which strikes the brickwork, and fills up the crevices. In lining the furnace, therefore, it is only necessary to build up the bricks by placing them one upon another, no fire-clay being needed; in fact, after a few weeks' working the interior will present a glazed appearance, forming one solid mass, and thus protecting the first row of tubes from the flames.

The internal face of the brickwork always remains in a semimolten state, forming a reserve of radiant heat, ready to be transformed into steam at a moment's notice, should there be a sudden demand.

This boiler compares very favorably in upkeep with any other boiler fitted with a mechanical stoker. It is found to be practically smokeless in operation, as only a film of grey dust is emitted from the stack.

The initial cost of the boiler is not heavy, when it is understood that neither economizer nor chimney-stack is needed; and the writer is of the opinion that in the larger sizes, it would not be more expensive in first-cost than other makes.

The advantages of this type of boiler may be summed up as follows: (1) High thermal efficiency, (2) smokeless combustion, (3) quick steaming, (4) flexibility in output, (5) small ground-space required, (6) no banked fires, (7) low radiation losses, and (8) the use of low-grade fuels.

INITIAL STRESSES IN STRUCTURAL STEEL.

By Joseph R. Worcester.

The subject of initial stresses in rolled members has received much attention in recent years, but no more than it deserves, for the reason that, under certain circumstances, it may result in very serious consequences.

A few years ago much attention was attached to a series of tests by Prof. Edgar Marburg, of the University of Pennsylvania (Proc. Am. Soc. Test. Mat., Vol. IX.), on I-beams of standard section and certain Bethlehem shapes, on account of the extremely low elastic limits reported. The cause of these low results was undoubtedly the initial stress near the junction of web and flange, produced by different rates of cooling of thick and thin metal.

More recently experiments by James E. Howard (Trans. Am. Soc. C.E., Vol. LXXIII.) and Professors Talbot and Moore, of the University of Illinois (Bulletin 44), have developed strikingly an early lack of proportionality of stress and strain in built-up columns, which can only be explained by internal initial stresses.

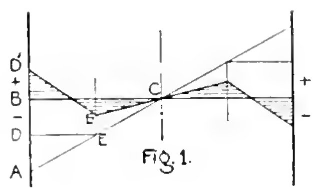


Fig. 1.

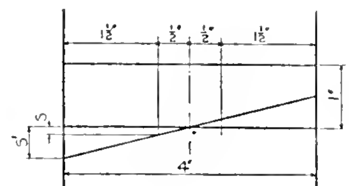

Fig. 2.

Another striking example of internal stress which has been known to many members of this Society has been in large I-beams which have suddenly, without provocation, split through a large part or the whole length of the web.

For many years it has been recognized that where steel is heated locally for forging there is likely to be produced a region between the heated and unheated portion where the metal is brittle and can be broken by a blow or shock. A striking instance of this came under the speaker's observation recently in the case of some 2-in. diameter steel truss rods which had been upset. One of these, in unloading from a team, had its upset end broken short off with a granular fracture. On testing the other rods, by striking the end with a sledge, it was found that several broke in the same way, while the rest could not be broken. A chemical analysis of one of the worst ends showed 0.408 per cent. C., 0.045 per cent. S., 0.065 per cent. P., 0.38 per cent. Mn., a result consistent with good metal. Though perhaps not so certainly established as other cases, it is quite probable that this fracture was induced by internal stresses caused by the local heating.

A similar effect in eyebars was noticed, soon after the introduction of steel into their manufacture, and led to the universal adoption of annealing furnaces long enough to anneal the whole bar at one time after forging. This practice has recently been proved by Mr. A. H. Emery to be of no benefit, as far as can be determined by tensile tests, as it decreases both the elastic limit and the ultimate strength, while no decrease in strength appears to follow from the local heat treatment, under direct tension as applied in the testing machine. It does not necessarily follow, however, that the annealing may not be a desirable precaution as a safeguard against shock.

Admitting, then, the prevalence of initial stresses, it is interesting to consider their origin with a view to guarding

* Presented before the Association of Engineering Societies.

against them where possible. When their origin is in some form of heat treatment, it is generally possible to overcome them by annealing, though this may not be the only or the best method.

When they are confined to members used in direct tension they may not be of serious import, because, on the application of stress to the member, the effect is to increase the initial tensile stresses already existing, reducing or neutralizing internal compressive stresses. As the applied load increases, a point is soon reached where the fibres carrying most of the tension reach the elastic limit and begin to stretch, after which a redistribution of stress occurs, spreading the stress over all the fibres equally.

A familiar example of this is in the case of a copper wire which may be coiled or crooked with internal stresses. We all know how if such a wire is stretched beyond the elastic limit all crooks immediately disappear. So with a steel member, if in tension it is in stable equilibrium, and a minute stretch can usually occur without harm to the structure.

With compression members, however, the case is radically different. In these, the first applied load, if initial conflicting stresses exist, tends to throw the whole member out of alignment. It is in unstable equilibrium, and the more it bows, the greater the danger.

One of the causes of initial stresses is cold straightening of metal before assembling. Cold straightening is, in reality, cold bending, and the following investigation is an attempt to determine the limits of internal stress which may be produced by cold bending.

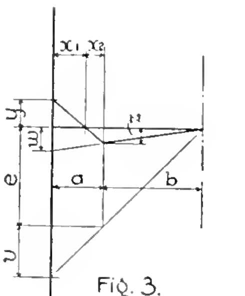

Fig. 3.

$$x_1 + x_2 = a \qquad [1]$$

$$\frac{x_1}{y} = \frac{x_2}{z} \qquad [2]$$

$$y + e = v + e - w \qquad [3]$$

$$\frac{v+e}{e} = \frac{a+b}{b} \qquad [4]$$

$$\frac{w}{z} = \frac{a+b}{b} \qquad [5]$$

$$y\frac{x_1}{2}\left(a+b-\frac{x_1}{3}\right) = (b+x_2)\frac{z}{2}\left(\frac{b+x_2+b}{2}\right)\frac{2}{3} \qquad [6]$$

Solving these equations, we obtain these values for y & z in terms of a, b & e:—

$$y = \frac{a(a+2b)}{2(a+b)^2}\,e \qquad z = \frac{a^2(2a+3b)}{2(a+b)^3}\,e\,.$$

It is well known that the material as it comes from the hot bed is almost always more or less out of line, and that in order to straighten it the most effective and simple method, and the one generally used, it to bend the member, in the direction opposite the initial curvature, enough so that when it springs back under its elasticity its alignment will be true. The effect of this bending beyond the straight line and allowing the elasticity to recover it to the correct point is to strain the outer fibres on each side beyond the elastic limit. The elastic recovery reverses the stress in the extreme fibres which have been overstraind, and leaves a condition of stress within the section something as shown by the diagram on the foregoing page.

This means that starting from one edge of the section we find at first a tensile fibre stress extending in a certain distance in constantly decreasing intensity until it reaches a point of no stress or a secondary neutral axis, beyond which the stress becomes compressive, increasing to a maximum at a point, the distance of which from the outer fibre is the same as that which limited the field of metal stressed above the elastic limit by the bending. From this point the compressive stress diminishes to the axis of the section, beyond which it becomes tensile again, increasing to a certain point from which it decreases again, again changing to compression at another secondary neutral axis and increasing in compressive stress until the opposite extreme fibre is reached.

In considering Fig 1, we see at once that with a symmetrical rectangular section we have two fields of tensile stresses and two fields of compressive stresses represented by triangles, and we find that certain assumptions may be made with regard to these fields which serve to fix their amounts.

In the first place, considering the effect of the bending, if the material was not strained beyond the elastic limit, the stresses on each side of the neutral axis would have been re-

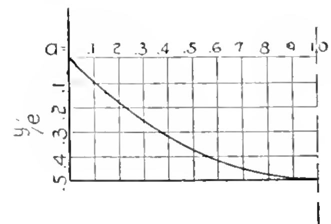

Fig. 4.

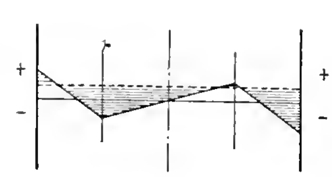

Fig. 5.

presented by a single triangle ABC. If, however, the stress AB is greater than the elastic limit of the metal, this triangle would be truncated by a line DE parallel to the cross section and distant from it an amount represented by the elastic limit of the material. When the bending stress is relieved, the line DEC assumes a new position D′E′C, the distance from D to D′ and from E to E′ being proportional to the distance from the neutral axis. This proportionality is one of the determining elements. Another is the fact that the total tensile stress multiplied by the distance of its centre of gravity from the neutral axis must equal the compressive stress multiplied by its axial distance. This is a necessary condition of equilibrium.

Lest it should be argued that the line DEC does not agree with the stress-strain diagram it should be borne in mind that in considering the elastic distortion we are dealing with an extremely minute deformation. Between adjacent planes of cross-section it is really infinitesimal, and any finite stretch would be so small as to produce practically no increment in stress. This consideration is valueless on account of its imaginary character. We might, therefore, without invalidating the argument, assume that we are considering the angle between two planes of cross-section separated by a finite distance, as, for instance, one inch.

Suppose, for example, a bar 4-in. by 1-in. bent edgewise, to a radius of curvature such that one quarter of its width along the neutral axis is still elastic and the balance, on each side, overstrained.

Referring to Fig. 2, the stretch S, at the limit of the elastic portion, will be about:

$$\frac{30{,}000}{30{,}000{,}000} = \frac{1}{1{,}000} \text{ inch.}$$

The stretch of the extreme fibre S′ will be:

$$0.001 \times \frac{1.5}{5} = 0.003.$$

The assumption is that the elongation of S′—S will not cause an appreciable increase in stress after the metal has reached the elastic limit.

$$S' - S = 0.003 - 0.001 = 0.002 = \frac{2}{10} \text{ per cent.}$$

If the gain in strength between the elastic limit and the ultimate is accompanied as it frequently is, with a stretch of 30 per cent., and we should assume the rate of gain propor-

tional, this stretch of 0.2 per cent. would mean an increase of stress of about

$$\frac{0.2}{30.0} \times 30{,}000 = 200 \text{ lb.}$$

But, the characteristic of stress-strain diagrams is that there is a sudden yielding accompanied by a very considerable stretch with no increase in stress or even a slight falling off. To be sure, in assuming any sharp angle in the diagram, there is a slight error, as the corner should be rounded. It would be more exact to say that the lines assumed are tangent to the curves, but the effect of this rounding may be disregarded without invalidating the theory. Referring to Fig. 3, the above assumptions may be expressed algebraically as follows:

Letting $a+b=1$, we find that the equation for y assuming a as a variable is a parabola with its vertex at the neutral axis of the section of ½e, the parabola passing through the origin. This equation is $y = \left(a - \frac{a^2}{2}\right)e$, or $2a - a^2 = \frac{2y}{e}$.

Expressing this result in words, it amounts to this: If a rectangular bar is bent so that it has any permanent set the internal maximum fibre stress may be obtained if we know to how great depth the outside portion of the section has been stressed beyond the elastic limit. The amount of this internal stress can never exceed one half the elastic limit, and between 0 and ½ e it varies according to the abscissas of a parabola of which the axis is the neutral axis of the section.

We may determine the depth to which fibres are stressed beyond the elastic limit, if we know the radius of curvature and the thickness or depth of the section. We know from mechanics that $\frac{1}{r} = \frac{e}{Ed}$, in which r is radius of curvature, e is elastic limit of the material, E is the modulus of elasticity and d is distance from the neutral axis to the extreme fibre. Using 30,000 for e and 30,000,000 for E, this formula becomes $r = 1{,}000d$. In other words, the distance from the neutral axis to the fibre which is strained just to the elastic limit will be one thousandth of the radius of curvature; hence, if we know approximately the radius of curvature, we can tell at once what part of the thickness of the section is not overstressed, and, subtracting this from one half the total thickness, can find a. Taking a practical example of this we should obtain the following results.

Assume a bar 3-in. by 1-in. to be somewhat crooked edgeways and to be straightened in a press. Let us assume that in straightening it is curved to a radius of 12 ft., a very moderate assumption.

The width of metal not overstressed would be $\frac{12 \times 12}{1{,}000} =$ 0.144 in. each side of the neutral axis.

$$a \text{ would therefore} = 1.5 - 0.144.$$
$$= 1.356 \text{ in.}$$

or, on the basis of $a+b=1$.

$$a = \frac{1.356}{1.5} \times 1 = 0.9.$$

From the diagram, Fig. 4, we find that under these circumstances y, the initial fibre stress, amounts to 0.495 e, tension on one edge, and compression on the other, or approximately to 15,000 lb. per sq. in.

This means that in a bar which is quite straight and wholly innocent in appearance there may exist a compressive stress along one edge of 15,000 lb. per sq. in., while along the opposite edge is a tensile fibre stress of an equal amount; in other words, an inherent tendency to bend out of line on the least provocation. This condition cannot be detected by any of the usual methods of inspection, but might be suspected if we knew its history.

It will be noted that the above analysis applies only to a rectangular section. In the case of an irregular section such as an I-Beam, it is evident that if the bending is in the plane of the web, a lesser stress in the extreme fibre will produce equilibrium on account of the decreased area of the section in the parts nearer the neutral axis. On the other hand, however, if the bending is at right angles to the web, the converse is true, and the extreme fibre stress will be greater proportionally, and may easily approach nearer to the elastic limit. The same is true of a bar with a circular cross section.

Let us now consider the practical effect of these internal stresses. Referring again to Fig. 1, we see that if we apply an axial stress to a member which is already subjected to this condition of internal stress the effect will be to produce a condition as shown by Fig. 5

In this case we see at once that the areas of stress will be unbalanced so far as the rotating moment is concerned. The effect of this unbalanced condition will be to produce a tendency to spring out of line. If the axial stress is in tension, this tendency is offset by the axial stress itself, and even in case the extreme fibre stress exceeds the elastic limit, a slight yielding of these fibres soon distributes the stress more uniformly and so no serious results can occur. But if the axial stress is compressive, the tendency to spring is very serious and immediately throws the strut out of equilibrium, so that the bad effect of the internal fibre stress is accentuated. If the elastic limit is passed, the buckling may even go on to the point of failure.

It is not the present purpose to enlarge upon applications of the above theoretical considerations, but perhaps enough has been said to show the tremendous importance of eliminating cold straightening so far as possible from the ship treatment of metal which goes into compression members.

A copy of telephone statistics of the Dominion of Canada just issued shows that the total number of telephones in service in Canada is 370,884, 212,732 common battery and 158,152 magneto. During 1912 there was an increase of 37,738 in the number of telephones operated by common battery, and an increase of 30,387 in the number operated by magneto. The total number of miles of wire is given as 889,572. This is divided into urban and rural as follows: Urban, 636,961; rural, 252,610. This indicates that there is one mile of telephone wire in use for every 8.1 of the total population of the Dominion, and one telephone for every 19.3. There was one telephone for every 2.3 miles of wire. The class of wire used was as follows: Galvanized, 271,191 miles; copper, 20,096; overhead cable, 232,393; underground cable, 364,875; submarine cable, 1,015. The aggregate capital expenditure in telephones is now placed at $46,276,851, though the cost of real property is placed at something over $10,000,000 beyond this figure. This works out to a capitalization of $124.75 per telephone in use. The gross earnings from all telephone companies for the year amounted to about $12,250,000, as compared with a little over $10,000,000 the previous year. Operating expenses were 74.0 per cent. of gross earnings as compared with 69.32 for the previous year. Gross earnings work out to $33.90 per telephone in use or $13.79 per mile of wire.

THE RECLAMATION OF SWAMP AND OVERFLOW LANDS.

Mr. E. T. Perkins, of the National Drainage Congress of the United States, gives an argument for national direction for swamps and overflow lands in the Journal of the Western Society for Engineers for February, 1913. A summary of the argument is as follows:—

The national problem of controlling and regulating the Mississippi, is only a part of the problem of our swamp and overflowed land of approximately 74,000,000 acres lying in almost every state in the Union. The vast benefits to be derived from the reclamation of this great area are too obvious to require comment. It is generally known that these acres possess wonderfully fertile soil, capable of producing great crops for many years without defertilization to any marked degree.

The United States Department of Agriculture touched on this subject in Circular No. 76, Office of Experiment Stations, on "Swamp and Overflowed Lands in the United States," issued in 1907. The circular (basing the acreage to be reclaimed at 77,000,000) states:

In those states where large areas of swamp land have been thoroughly drained by open ditches and tile drains, the cost ranges from $6 to $20 per acre, while in places where tile drainage was not required the average cost has not exceeded $4 per acre. Judging from the prices which prevail in a large number of these districts where work of this kind is being carried on, it is safe to estimate that the 77,000,000 acres of swamp can be thoroughly drained and made fit for cultivation at an average cost of $15 per acre. The market value of these lands in their present shape ranges from $2 to $20 per acre, with an average of probably $8 per acre. Similar lands in different sections of the country that have been drained sell readily at $60 to $100 per acre at the completion of the work, and in many instances, when situated near large cities, they have sold as high as $400 per acre. To determine whether or not it will pay to drain these lands, we have but to consider the following figures:

Cash value of 77,000,000 acres after thorough drainage, at $60 per acre		$4,620,000,000
Present value of this land at $8 per acre	$ 616,000,000	
Cost of drainage at $15 per acre	1,155,000,000	
Value of land and cost of draining		1,771,000,000
Net increase in value		$2,849,000,000

These figures, though large, are not fanciful, but are based on results obtained in actual practice in different sections of the country where work of this kind has been done.

Since this circular was issued by the Department of Agriculture in 1907 many swamp and overflow acres have been reclaimed; the cost of reclamation undoubtedly has risen with the general increase in cost of things, but the value of the land also has risen, so it may be conservatively supposed that the net result as figured in 1907 is approximately the proper figure for to-day, upon the assumption that 100 per cent. of these lands could be reclaimed, which of course we know to be impossible.

Now, the reclamation of the great bulk of swamp and overflowed acres is largely dependent upon the control and regulation of the nearest main river system and its tributaries.

From the headwaters to the mouth it is not possible to reclaim or correct one part without at the same time exerting some influence, either for good or bad, upon the other portions.

This is a natural fact. When we try to subdivide one of the problems and solve each subdivision from our own limited viewpoint, and for our personal, selfish interests, we are making trouble for ourselves or someone else, or both. We are doing more; we are violating the laws of Nature which, before the arrival of man, establishel these drainage basins, and provided these drainage problems for us to solve. There is only one right solution to every problem; there may be found ways to find many answers, but only one of these can possible be the best.

Can we establish arbitrary boundaries, often in ignorance of existing physical conditions, ignoring natural problems and necessities, and say: "Here, this political body shall have jurisdiction, and there, that one?"

Physical, economic, social reasons demand that the reclamation of these 75,000,000 acres of swamp and overflowed lands, and the control of the waters that cause them, must be undertaken in a broad and comprehensive way—in a national way—and this cannot be done offhand.

There is no cure-all, no panacea. Careful investigation and study must be had that there may be developed a plan founded upon justice, equity, and good engineering. It must be constitutional, not only as regards the nation but as regards each state affected. In addition, every beneficiary, nation, state, corporation, individual, must in due proportion bear the expense of the improvement producing that benefit, either direct or indirect. With the insufficient data available I would hesitate to accept or reject at this time any particular plan.

But how shall we put into effect this general plan after we shall have formulated it?

The several states were granted all swamp and overflowed lands remaining unsold within their borders after September 28, 1850, for the specific purpose that the proceeds of their sale should be used in reclaiming them. So far as I know, Florida is the only state that is complying with the provision of the act, and except in Florida, practically all of these swamp lands have passed into private ownership in lots ranging from a few acres to many thousands, with the owners scattered about the world.

This condition of ownership is one of the difficulties that must be contended with. The Reclamation Act was designed to reclaim the federal lands of the West, and when private holdings were taken into a project it was by mutual consent and on a partnership basis. The government brings the water to the land after a certain percentage of the land owners in the project have agreed to join in its reclamation. No one is compelled to accept the use and benefit of this water if he has not so agreed, nor is he apt to be benefitted individually unless he does pay.

In the case of swamp and overflowed lands, however, it is not practical to drain or levee part of the land without affecting the rest; each tract of land will be benefited whether the owner desires such benefit or not, or whether he wants to pay his share of the cost of reclamation. For this reason most of the states containing swamp and overflowed lands have passed drainage laws allowing certain majorities either of lands or owners, to form drainage districts and so compel all persons owning lands within the district that may be benefited, to help pay the costs of reclamation.

Just as the states can help the individual land owners to organize their drainage districts, so can the federal government, in planning a complete system covering the entire drainage basin, by means of complete surveys and plans, work out efficient and harmonious plans for each individual

project, if desired, and have each individual project harmonize with the general plan covering the entire drainage basin. This, I hold, is a national duty and a national necessity.

TYPHOID FEVER IN PITTSBURGH.

Before the installation of the water filtration works Pittsburgh had a typhoid fever death rate of practically double that of any other large American city. As set forth in the last report of Mr. C. A. Drake, superintendent of filtration, the first filter unit was started in December, 1907. All of peninsular Pittsburgh was receiving filtered water exclusively in October, 1908, and all of the south side, except the 20th ward, in February, 1909. The present typhoid fever death rate in the filtered water district shows that the purified water supply may well be included among the very safest supplies of the world.

The following table, showing typhoid fever statistics in certain important American cities, shows what the Pittsburgh filtration works, under skilled supervision, and with the final filtered product sterilized with hypochlorite of lime, has done in the line of cutting the typhoid fever death rate to a practical minimum. The results achieved at Pittsburgh in this line are by far the most gratifying and spectacular ever noted in the history of water purification in this country.

The National Pipe and Foundry Company, Limited, whose head office was formerly in the Board of Trade Building, Montreal, has moved to larger quarters at 802 McGill Building, McGill and Notre Dame Streets, Montreal. The company's works are at Alexandria, Ontario, where they make tanks and wooden water pipe in all sizes from 2-inch to 24-inch for waterworks systems, domestic supply and hydraulic mining; insulated wire conduits, steam pipe casings and acid-proof pipe for mines, tanneries and pulp mills.

COAST TO COAST.

Halifax, N.S.—The completion of the three transcontinental railway systems by providing what they lack—a properly equipped Atlantic terminus—is the central idea of the Dominion government in spending twelve million dollars on new terminals at Halifax, contracts for which, it is expected, will be let shortly. Halifax thus becomes one of two great winter ports of Canada. Possessed of an unrivalled harbor which requires no dredging or improvements to navigation, it has lacked, always, those terminal facilities which are absolutely essential to the development of any port. Its present docking arrangements are adequate only for local shipping and go only part of the way in accommodating the present ocean trade. There is no provision either for the congestion that ofttimes arises or for that expansion which will be the resultant of the country's growth. Three transcontinental railways point to Halifax—the National Transcontinental and the Canadian Northern are definitely planned to go there, while the Canadian Pacific is equally anxious to have an independent entrance, through fuller running rights on the I.C.R. or a line of its own. The volume of traffic these roads will carry to Halifax necessitates, obviously, the enlargement of "the spout." It is considered absolutely essential to the proper completion of these great national undertakings that their ocean terminals should be commensurate to the requirements of that great and voluminous traffic they are carrying now, or will carry in the near future. In view of these considerations, the national importance of the Halifax work is apparent.

Montreal, Que.—That the by-law regulating street traffic is to be drastically remodelled, was announced at the city hall recently. The amendments to the by-law will be of such a nature that they will affect not only drivers of vehicles, autos, etc., but pedestrians as well. It appears that during his visit to Chicago last week Mayor Lavallee was much impressed with the system in vogue there. It is very simple yet very effective. At the densely congested streets two policemen are stationed. All vehicular traffic is stopped by the sounding of one whistle; while two whistles permit it to proceed. So soon as the one whistle is heard pedestrians make haste to cross the streets, but when two whistles are sounded they remain on the sidewalks till they hear the one whistle again. So familiar have these whistles become in Chicago that they are instantly understood and the system is said to work even better than the holding up of the policeman's hand. It is this system that Mayor Lavallee will inaugurate in Montreal. Chief Campeau is to be called before the Board of Control and given instructions in regard to the new order of things.

Montreal, Que.—One hundred thousand dollars has been appropriated in the sundry Civic Bill which has passed the Senate at Washington for the American end of the expenses of the International Joint Commission which is now engaged in one of the greatest surveys ever attempted between Canada and the United States. The commission has settled the Livingstone's Channel and the Rainy Lake question, and is now working on a big problem in connection with the Lake of the Woods, etc., and also on several complicated questions of pollution of waters at narrow points along the Great Lakes. The Lake of the Woods problem involves the interests of $75,000,000 of investment on the American side of the big sheet of water. The two governments want to know what is the best level to be established to serve the interests of all concerned. The sewage and pollution question is of vital interest to the region about Detroit, where the sewage of

600,000 persons is being dumped into the Detroit River, and on the Canadian side pollution from about 40,000 people is coming into the same water. The same condition exists at the lower end of Lake Erie and in the Niagara River, where the population of Buffalo is responsible for the pollution. So it is at Tonawanda and North Tonawanda, and at Niagara Falls city. It is claimed that the sewage spreads all over the lake, and that the St. Lawrence is polluted before it leaves the boundary line also.

Fort William, Ont.—The Dominion Government is maturing its plans for the building of interior terminal elevators in the West. The wheat production of the prairie provinces is increasing at such a rate as to cause a great strain upon the railways, despite their constant construction and the provision of new facilities at Port Arthur and Fort William. In addition to the large elevator now being built at Port Arthur, with a capacity of three and a quarter million bushels, and the rushing of work on the Hudson Bay Railway, the need of interior elevators is felt for relieving the congestion. For this purpose, an item is being put in the supplementary estimates. When these elevators are built all grain going in and coming out of them will be weighed and inspected and can be sold on inspection. This will enable the owners of grain to get a negotiable warehouse receipt upon which they can borrow money from the banks or sell the grain on the markets. The elevators will be so equipped as to treat wet and damaged grain, and will be of particular utility in providing a further reserve storage capacity. It is intended to build a few elevators at once to find out exactly what good they produce. If the results are satisfactory the government then will go further.

Toronto, Ont.—The Ontario Government is embarking upon extensive investigations in the matter of sewage disposal and the protection of the fresh water supplies of the province from contamination due to careless or unskilled methods. With the fact in mind that every provincial municipality located near lakes or rivers is facing serious problems of this nature, Dr. J. W. S. McCullough, chief officer of health, will visit in the summer months several places in Great Britain and the continent to discover assistance in solving the difficulties which come before his department. In view of the action taken by the provincial board, acting in conjunction with the International Joint Commission, to examine the boundary waters and discover the prevalence of pollution, a report will be forthcoming in November. The knowledge will then have been acquired by Dr. McCullough as the most practicable manner of dealing with the general situation. Legislation improved and amended at the recent session places within the jurisdiction of the board power to force instalment of whatever water systems they consider best, and if a purification plant or a sewage treating plant is thought necessary the municipality concerned will be obliged to install it without appeal to the people. This obviates much of the trouble which has occurred in unwilling towns in the past. Dr. McCullough will visit London first and go thence to Germany and France. He leaves Toronto during the week of July 1, and the trip will consume two months.

Quebec, Que.—In addition to the objections from the government of Saskatchewan to Hon. Frank Cochrane's bill providing for federal subsidies for the improvement of highways, the government of Quebec, through Sir Lomer Gouin, has now come out with a severe criticism of the bill as passed in the commons. In an official statement Sir Lomer says that it is to be greatly regretted that the federal government has not amended the bill in line with the demands of the opposition and of the senate. "I am," he says, "an advocate of good roads and I very greatly desire to see our roads improved as much as possible. But the federal government's bill does not satisfy me. I find it even dangerous in principle. It does not satisfy me because it does not insure an equitable distribution among the provinces of the moneys which parliament may vote. The ministers, it is true, have told us that according to the subsidy act these moneys will be distributed among the provinces according to population but the actual text of the law has not been worded so as to insure this. Moreover governments pass out of existence and the successors of the Borden government will not be bound by the word of the present prime minister. Why should not the present government follow the example of the fathers of confederation? Why should it not incorporate in the good roads bill the same principle which had been incorporated in the bill with regard to the advancement of agriculture? Moreover, this bill appears dangerous to me for it infringes the rights of the provinces and tends to narrow local autonomy. Article 92 of the B.N.A. Act specifies that the provinces shall have jurisdiction over all local undertakings but in what position would the provincial administration find themselves if the good roads bill became law in its present form? They would simply have to give up their rights and their prerogatives in order to get the subsidy which would be offered them or else they must give up the subsidy.

Montreal, Que.—A Town Planning Bill, under which every municipality would be compelled to draft plans of its future development, is strongly advocated by Controller Lachapelle. "Town planning," he said, "is to me the problem of the hour. The way building operations are carried on in the suburbs is a disgrace to the city. There should be a definite plan for the whole island of Montreal, homologated by the legislature, so that building would have to follow its lines; and a better-laid-out city would be gradually evolved. I think it would be a good idea to get the services of an expert, say from Europe, and give him a summer in which to draft his plan. The United States Government recognized the need of building its capital on a definite plan, and Washington is the pride of every American in consequence. The necessity of compelling municipalities to build along definite lines has been recognized by a number of European governments. They have made it compulsory for towns of over 5,000 inhabitants to build and expand on a definite scheme. We need, too a campaign of publicity to instruct the people and to bring before them the necessity of town-planning. We are annually faced with an increasing tide of immigration. The country population is moving into the city, and unless we do something quickly it will soon be almost impossible to do anything really effective. It is no use improving a little here and a little there. It is only wasted time. What we want is a definite plan."

Quebec, Que.—"This road will mean easily $1,000,000 annually to Quebec," said Mr. Geo. A. McNamee, secretary of the Automobile Club of Canada, as the first party this year to officially inspect the new King Edward highway passed along its route. Mr. McNamee was representing the club and Dr. Desaulniers, of St. Lambert, M.L.A., for Chambly, was the government for the time being. It was the first official look over the completed good road, on the way to Rouse's Point, N.Y. In all nearly twenty miles of the new work is now done, of the forty-five-mile long King Edward Road. In fine weather the new road is comfortably passable from Victoria Bridge to the New York state border line. In bad, wet weather the old St. Lambert to Laprairie section would not be any more "available" than it has for years in the past. But apart from the first twelve miles the motorist really has no great "kick" coming, especially when he looks back a year or more. Where sections of the new road

have been built driving is a delight. The Lapresse road, one mile in length, was completed last year. That is the first mile in the "cut" through to St. Phillippe getting away from the impossible Laprairie section. The remainder of the nine miles is fast being constructed and will be completed, it is thought, by August. By that time all the various sections yet untouched will be linked up with the already completed good sections, and the good road will exist in its entirety. The last contracts for the work were signed immediately on the return from abroad of Sir Lomer Gouin, premier of the province, and the completion of the new highway is going on rapidly.

Victoria, B.C.—Now that Victoria is looking forward to the construction of one of the largest graving docks in the world at Esquimalt, some notes about the Gladstone dock at Liverpool, which is the largest in existence, will be of interest. The capacity is about 50 million gallons, and the cost was about $2,430,000, or about that of the proposed dock here. Work began at Seaforth in September, 1910, and after the necessary bank had been erected to keep the water out, in January, 1911, the work of excavation was begun on the shore proper. A commodious dock over 1,000 feet in length has been constructed, lined with half a million tons of concrete, with granite coping. The striking feature lies in the fact that the new receptable may be used not only as a graving dock, but as a wet dock, and that achievement is an interesting one. The ordinary graving dock is constructed in quite a different way from the wet dock. The sides slope and are provided with steps to facilitate the shoring of the vessel. The Gladstone dock is planned differently; it is so constructed that the giant vessel can either discharge cargo, as in the ordinary wet dock, or be repaired when the water has been run off. Exceptional circumstances necessitated the experiment, the plans for which, prepared by A. G. Lyster, were carried out by W. H. Jones. Dock gates were found to be impracticable. Two sets would have had to be fixed, and to obviate this it was decided to provide a sliding caisson. The caisson, when not in use, is kept in a chamber that runs off the dock, and is operated with ease. In another chamber the pumping machinery is installed. A commodious place, very like a small dock, it will be fitted with five Diesel engines, each of a thousand horse-power. The employment of oil engines is an innovation, for all the other pumping machinery on the dock estate is dependent on steam.

Edmonton, Alta.—Regarding the Rabbit Hills gravity system the Montreal experts have presented the following report: The system seems to have a number of points which would immediately commend themselves, namely, a natural intake which would form a rough settling basin in the river. Within a distance of a mile and a half of this point on the river there is a hill 120 feet above the general level of North and South Edmonton. Nearby there is a much smaller hill 32 feet higher than the former one. There is said to be in the immediate vicinity a supply of lignite which would enable the coal to be sent direct from the mine south to the boilers in the pumping station at the riverside. By locating the reservoir on the larger hill and running liberally proportioned mains to the city it would be possible to deliver water from this source at a pressure of, say, 30 or 35 pounds per square inch at the centre of the city on the general level. It would doubtless be necessary to raise this pressure in the city by booster pumps, although we have not included a price for such a pumping station in the estimates. On the plan we have indicated an intake and pump-house at the approximate elevation of 2,070, which would deliver the water through a pressure main to the raw water reservoir on the top of the highest hill, a distance of about two and a half miles through an elevation of 322 feet. From the raw water reservoir the water would pass by gravity through the filters to the main reservoir on the general elevation of 2,360, whence it would be delivered to the city through a double 36-inch pipe line about seven miles in length. Such a system would have the advantage of uniform continuous pumpage at the pump house, and it would give a low but uniform pressure in the pipe line leading to the city. The details of the estimate of cost of the Rabbit Hills gravity system are as follows: for a population of 100,000 the estimated cost is $6,263,133; a population of 150,000 will cost $7,189,983, and 200,000 will cost $9,447,172.

PERSONAL.

F. S. LAZIER, of the Department of Railways and Canals, who was stationed at Campbellford until recently, has just returned from an extensive tour of Western Canada. Mr. Lazier is now making Toronto his headquarters.

K. A. DUNPHY has been appointed resident engineer of the Canadian Pacific, District No. 2, Alberta division, with headquarters at Calgary, Alta., in place of J. Robertson.

MR. W. D. MURRIN, of London, Eng., formerly with the London United Railway, has been appointed mechanical superintendent of the entire system of the British Columbia Electric Railway Company, succeeding Mr. S. P. Thompson, of New York, who resigned.

MR. T. KENNARD THOMPSON, the well-known consulting engineer of New York, has been re-elected president of the Canadian Club of New York for another year.

MR. D. McD. CAMPBELL, city engineer of Sydney, N.S., has resigned owing to ill health, after serving the city for the past thirteen years.

MR. GEORGE H. TOD, of Toronto, who is the Canadian representative for Ashworth-Parker engines, Bennis mechanical stokers and Broadbent's cranes, capstans, etc., is making a six weeks' tour of Western Canada. Mr. Tod recently opened a western office at 601 Union Bank Building, Winnipeg.

MR. C. M. WATERMAN, manager of the Eugene Dietzgen Company, Limited, Toronto, is making a month's trip through Western Canada. Mr. Waterman will call on his return at his firm's Chicago factory, which is making every effort to fulfil all the requirements of the Canadian field. Mr. Dietzen, a brother of the founder of the firm, and one of the present heads of the business, will make an extensive trip through Canada later in the season.

OBITUARY.

There has just died at Hayward Heath, forty miles south of London, an Englishman whose name is known to railroad men throughout Canada; John Saxby, of the firm of Saxby & Farmer. He died, at the age of 92, on Wednesday, April 23. The first patent bearing Saxby's name was taken out in 1854, for a signal lamp with a movable inner case which changed the color of the light as the signal arm moved up or down. This was the joint invention of Saxby and W. V. Greenwood. Saxby's first interlocking patent—the invention which has made his name a household word among signal men all over the world—was taken out in June, 1856. His first installation was an interlocking of eight signals and six switches at Bricklayers' Arms Junction, where fifteen years before the semaphore designed by Gregory had been first introduced. In 1860, Austin Chambers patented an improvement on Saxby's idea, but a few months later Saxby made still further improvements, and thereafter kept the lead over all his competitors. His patent for preliminary latch locking

was taken out in March, 1867. The firm of Saxby & Farmer was established about 1860. W. M. Punter is the Canadian representative of the firm with headquarters at Montreal.

ONTARIO HEALTH OFFICERS' ASSOCIATION.

The second annual meeting of the Ontario Health Officers' Association will convene at the Parliament Buildings on Thursday and Friday, May 29 and 30th.

Amongst those who will address this meeting are G. C. Whipple, Professor of Sanitary Engineering, Harvard University; Dr. Chas. A. Hodgetts, Medical Advisor to the Committee of Conservation; Dr. Chas. J. Hastings, Medical Officer of Health for Toronto; Lieutenant-Colonel Laurie, Port Arthur, and many others. It is provided by the statutes that all medical officers of health shall attend—as there are about 850 of these officers in the province, the attendance should be a large one.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25, Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE CANADIAN FORESTRY ASSOCIATION.—National Convention will be held in Winnipeg, Man., July 7-9. James Lawler, Secretary, Canadian Forestry Association, Canadian Building, Ottawa.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held at Chicago, Ill., Feb. 16-20, 1914. Secretary, E. E. Kraus, Harrison Bld., Philadelphia, Pa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—176 Mansfield Avenue, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, A. B Lambe, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Muckleston; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 534 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson Sask.

THE ALBERTA L. I. D. ASSIOCATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa, Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kehlor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Edmund Burke; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

TECHNOLOGY CLUB OF LOWER CANADA.—President, F. E. Came; Secretary-Treasurer, E. B. Evans. Meets twice yearly.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

THE LAYOUT OF A SMALL RIVER CROSSING

By C. D. NORTON.

The completed bridge, as shown in Fig. 1, is 650 feet from ballast wall to ballast wall; five 40-foot towers being connected with six 75-foot D.P. girders; height of water-towers, 75 feet. An ideal location (Fig 1) made it difficult to lay out, owing to the steepness of the banks and to the fact that each abutment stood on a promontory; added to which there was 300 feet of water in the middle.

The location tangent was established and chainage between hubs checked by a rough triangulation, a topographical sketch made, and conditions determined the base line as shown. (Fig. 2). Hubs were set every 10 feet and a double one at 100 feet for plumbing down; each set of 10 being levelled, the total drop in the 200 feet being about 5 feet. This base line was measured with with a 100-foot band chain and the three angles were repeated four times on each quadrant. A tabulation showed any radical errors and the average for each angle was taken out to 15 seconds.

Fig. 1.—Showing Completed Bridge.

Having determined the distance between two hubs which were approximately 650 feet apart, this exact distance was staked and checked by the same method. At a later date, when the pond was dried, the distance taped was found to be .06 foot shorter than the distance triangulated, a discrepancy due to the fact that the heavy band chain could not be stretched to its proper length without supports. Six hubs were then set on banks for the line of the pedestals from each side was chained separately. The face of ballast walls and centre of pedestals was referenced at right angles by hubs set out closer than 100 yards, one in fact being one-quarter of a mile up the valley. This completed the layout.

The abutments were checked every 5 or 6 feet during erection, tbe carpenter being given the centre line and face of ballast wall.

The depths of the pedestals were approximately determined by soundings, and staked accordingly. After tbe footings were in, hubs were set on the centre and reference lines, an intersection obtained with fine fishing line, and these lines transferred to the footing, on which the base of the foustoum was staked out. When the form was built the top was checked in the same manner. After the concrete was finished centres were marked on the pedestals from the reference points and checked with tape. On all important lines, wherever possible, foresights were set to eliminate double centering and to dispense with having to send a man around the dam to give point.

The first levels were, of course, the check levels over the section, when bench marks were set on each bank and at water level. Bench marks were then set every 12 or 13 feet down the banks and levels taken four times. These were tabulated, showing the differences between back and foresights which was the difference in elevation between benches and established a definite relation between them independent of initial or accumulative errors, any radical difference was eliminated and a mean struck which gave the elevation for the bench marks. Afterwards, whenever levels were run, the work was checked on to the next bench mark and the book elevations marked on the same sheet, thus obtaining an average in which final elevations were correct to within .01 foot. To set levels for the bridge seats temporary pillars were set on each side of the abutment and the height, some 30 feet, taped up, a line joining the points at the top being checked with a carpenter's level.

Elevations were, of course, given for the top of the pedestals, but owing to the shrinkage of the concrete and the varying temperaments of the men who floated the tops, the finished work varied as much as .05 high or low. The base of the columns was marked on tbe pedestals, and levels taken at each corner. These were tabulated in sets of four for each pier, and a mean struck which gave the least chipping, a difference of .01 in 75 feet being inappreciable. With an improvised target rod (a pencil point on a picket) the four corners of each seat were chipped to .001 foot and then

levelled by a stone mason, any low pedestals being chipped for to use a plate.

The foregoing may seem rather elaborate for a small bridge, but as neither the foreman in charge or the carpenter had done any large concrete work before it was none too much, and the end justified the means, for when the bridge

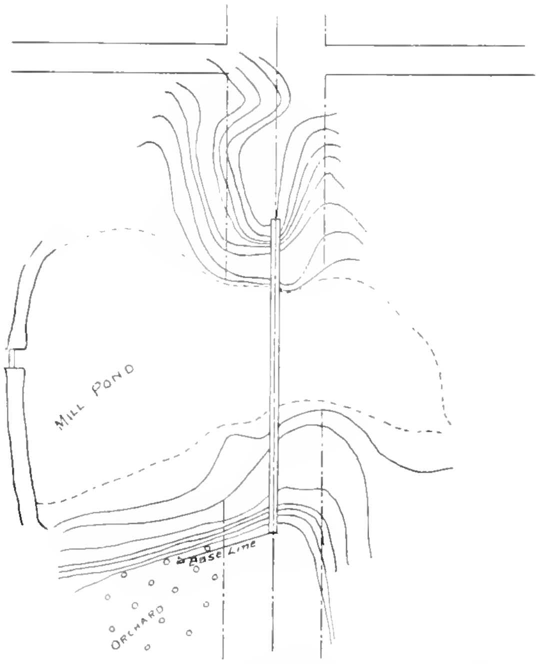

Fig. 2.—Layout of Small River Crossing.

company laid track, spiking to centre of girders, there was no need of relining when the bridge was finished.

The instruments used were a 5-inch transit reading to minutes, a 14-inch dumpy level, a self-reading rod graduated to half tenths, and a band chain.

AMERICAN WATERWORKS ASSOCIATION.

The thirty-third annual convention will be held at West Hotel, Minneapolis, Minn., June 23rd to 27th, 1913.

The following papers are scheduled: "The Diesel Engine for Waterworks," by Edward S. Cole; "Waterworks Special Franchises," by Henry DeForest Baldwin; "Reforestation and General Care of Watersheds," by Ermon M. Peck; "The Bacterial Count on Gelatin and Agar Media and its Value in Controlling the Operation of Water Purification Plants," by James M. Caird; "The Tuscaloosa, Alabama, Waterworks," by Prof. Edgar B. Kay; a paper on filtration, by George W. Fuller; "Charges for Public Water Service to Private Fire Protection Systems," by W. E. Miller; "A Reasonable Basis for the Determination of Charges for Private Fire Protection," by Leonard Metcalf; "Metering Private Fire Services at Kenosha, Wisconsin," by August Baltzer; "How a Private Fire Service Polluted a Public Water Supply and Some of the Consequences," by Robert J. Thomas; "Modern Filter Practice," by Nicholas S. Hill, Jr. "Gravity Water upply at the City of Manila, Philippine Islands," by H. E. Keeler; "Power for Pumping Derived from Refuse," by E. H. Foster; "Pumping Engines," by L. E. Strothman; "Ground Water Supplies," by Charles B. Burdick; "Rates and Rate Making," by Halford Ericson.

On Tuesday and Thursday evenings illustrated lectures will be delivered by Edward Wegman and Dr. William P. Mason.

There will be excursions on Wednesday and Friday afternoons.

NOTES ON SEWAGE DISPOSAL.

By Geo. W. Swinburne, M. Am. Soc. C.E.*

The liquid portion of sewage is not, to any appreciable extent, beneficially affected by being subjected to tank treatment. But, in addition to its dissolved impurities, sewage carries suspended solids, some of which can be eliminated by efficient tank treatment, and others which, under practical working conditions, are not depositable by sedimentation alone.

The operation in ordinary settling, or sedimentation, tanks is a comparatively simple one, since there are but two forces at work, the forward movement of the sewage and the force of gravitation acting on the suspended solids. These solids will be deposited at variable distances along the tank bottom, forming a gradually rising floor of sludge, diminishing the liquid capacity of the tank, increasing the rate of flow of the sewage, and finally causing a greater proportion of suspended matter to pass out with the effluent than is consistent with successful operation. When this condition is reached the tank should be put out of commission, emptied and cleaned.

In septic tanks the decomposition of the sludge results in the addition of a third force. It is often assumed that septic action results in the liquefaction of the organic portion of the sludge, but, while some liquefaction does occur, the result is essentially a gasification. These gases work in opposition to the force of gravitation acting on the suspended solids, and are the chief cause of the large amount of finely divided suspended matter found in septic effluents.

Since septic tanks have a longer sedimentation period and a greater sludge storage capacity than plain sedimentation tanks, the interval between cleanings is naturally longer, but the final result, putting the tank out of commission for emptying and sludge withdrawal, is the same in both cases.

Following a careful study of the results obtained with the two-story tank at the Lawrence Experimental Station of the Massachusetts State Board of Health and an exhaustive investigation of the conditions in which suspended matter is found in sewage, Dr Wm. Owen Travis, of Hampton, England, designed what is now known in England as the Hampton, or Travis, Hydrolytic Tank and in this country as the Hampton Sedimentation Tank. The results sought in designing this form of tank may be stated as follows:—

(1) To effect the sedimentation of the depositable solids of the sewage in such a manner as to maintain continuously the predetermined capacity of the sedimentation chambers.

(2) To increase the sedimentation efficiency and remove the liquid products of the decomposition of the deposited solids by causing a minimum proportion of the sewage to flow into and through the reduction chamber.

(3) To separate the opposing forces of gravitation and gaseous eruption by confining these operations to separate compartments.

(4) To provide for the removal of sludge at will and without interfering with the continuous operation of the tank.

The first tank of this type was constructed in 1904 at Hampton, England, to relieve the rapid clogging of the primary contact beds. An official report by Mr. J. H. Johnson, M.S., F.I.C., London, England, covering a period of six months' operation of this tank shows an average retention of 90 per cent. of the suspended solids of the raw

* Mr. Swinburne, to whom we are indebted for the compilation of the above notes, is chief engineer of the Sterilization Company, Newark, N.J.

sewage. Referring to a later and much larger installation at Norwich, England, Mr. Arthur E. Collins, Mem. Inst. C.E., City Engineer, Norwich, states: "The operation of the tanks in Norwich has been uniformly successful. The average removal of solids amounts to between 90 and 94 per cent. of the total contained solids of the crude sewage."

The tanks at Norwich are divided into three longitudinal compartments, of which the two upper are for the sedimentation of the sewage and the lower one for the collection and retention of sludge. The sedimentation chambers receive the entire volume of sewage, the greater portion of which traverses their full length and is discharged over weirs into the effluent channel. A small portion of the sewage descends through openings at the bottom of the sedimentation chambers, carrying with it the accumulated suspended solids, passes through the reduction chamber at greatly reduced velocity, and deposits its burden of suspended solids in the sludge pockets at the bottom of the chamber.

Any action in the reduction chamber will be similar to that in a septic tank, but in a more or less modified form, depending on the length of time the sludge is retained. With long sludge retention there will be the same formation and eruption of gas and resulting disturbance of the sludge, which, however, has no effect on the liquid flowing through the sedimentation chambers. Following such eruptions, the reduction chamber effluent will carry some of this disturbed deposited matter out of the chamber. These solids are eliminated in the small up-flow chamber through which this effluent passes.

Owing to the fact that English sewage is at least three times as strong as American sewage, it is commercially impossible to eliminate from American sewage by sedimentation alone as high a percentage of suspended solids as is stated above. All the available data indicates very strongly that under average American conditions the sedimentation chambers of two-story tanks should have a capacity of from one-tenth to one-eighth of the total daily flow of sewage. With an average retention period of from two and one-half to three hours the Hampton tank will show an elimination of suspended solids of about 65 per cent.

Sludge storage capacity should be determined in each case by such local conditions as climate, proposed method of sludge disposal or utilization, subsequent treatment of the effluent, etc.

The electrolytic treatment of sewage is not a new idea; Webster patented such a method of treatment in England nearly twenty-five years ago. Electrolytic sewage treatment works which seem to follow Webster's method in a general way are in operation at Santa Monica, Cal., and at Oklahoma City, Okla., but in neither case is any attempt made to clarify the sewage nor to obtain the benefit of the secondary, or time, reactions, which would materially reduce the cost of operation.

There are many cases in which a well-clarified effluent, if free from pathogenic germs, would meet all reasonable requirements. In such cases the sewage, or so much of it as may be necessary, can be subjected to an efficient preliminary electrolytic treatment and then passed through a Hampton tank to allow time for the secondary reactions and for clarification. Electrolytic treatment not only produces a powerful germicide, sodium hypochlorite, from the salts which are always present in sewage, but it also serves to coagulate the finely divided suspended solids, or colloids, and the simpler forms of dissolved organic matter, which can then be eliminated by sedimentation. Furthermore, since sedimentation is much more rapid after electrolytic treatment than under natural conditions, a material reduction can be made in the capacity of the sedimentation chambers without reducing the percentage of clarification.

This combination of electrolytic and tank treatment makes it possible to eliminate from 80 to 90 per cent. of the suspended solids of the crude sewage, make an appreciable reduction in the dissolved solids, and produce an effluent which is well clarified, odorless and free from pathogenic germs. The danger of such a plant ever becoming a local nuisance is reduced to a minimum.

DISPOSAL OF REFUSE IN TOWNS AND CITIES.

Refuse disposal is usually a serious problem for the small city or town to solve. In such cases public incinerators are not always economical and the ordinary dump needs careful regulation to prevent it becoming a nuisance.

Burning or burying is the most desirable method of disposing of ashes, rubbish, manure and garbage in cities. Of these, burning is the most sanitary, and no other means should be used in cities having a population of, say, 20,000, or more. Refuse incinerators are of two main types (1) the coal-fired or "low temperature," and (2) the high temperature. The latter is designed to handle mixed garbage without the use of coal. Very few of these have as yet been installed, and their advantages have not been entirely proven. For the coal fired incinerator a long-flaming coal of good quality is essential. This, of course, makes the cost of operation all but prohibitive for most small cities and towns.

In such cases, other means of refuse disposal must be obtained. To simply dump garbage in an unrestricted manner on some vacant lot should be classed as a criminal offence, and punished accordingly. The practice of burying refuse, where it is carefully carried out, is usually found to be cheap and at the same time effective.

The principle upon which refuse burial rests, especially as applied to garbage, is, primarily, a bacteriological one. The action of the soil bacteria is to mineralize the organic matter in the refuse. In order to prevent the occurrence of putrefactive or other objectionable odors the mineralizing process must be carried out in the presence of sufficient oxygen or air. To secure these conditions the following points should be observed: (1) The garbage should not be buried too deep, nor should it be spread in too thick a layer on the ground. (2) The ground used should be sufficiently porous and well drained to admit the air readily. (3) The garbage should be mixed with enough other refuse to prevent overloading the soil.

These conditions are obtained in different ways. In some cities the refuse is spread on the ground and then ploughed under. Another method is that of digging a trench, covering each day's collection of refuse with the soil, removed for the next day's supply. In any case, refuse that can be burned should be so treated and garbage and other organic waste can be more effectively handled by mixing it with other waste such as ashes, street sweepings, etc. It is claimed that 1.5 acres are necessary to handle each daily ton of garbage permanently. The soil can be re-used at the end of two years.—Conservation.

Three free scholarships, each covering four years' tuition in the Faculty of Applied Science at McGill University, have been offered by the Grand Trunk Railway Company to apprentices and other employees under twenty-one years of age, sons of railway employees. The competitive examination will be the regular university matriculation examination, beginning June 12th. The three candidates making the highest scores will receive the scholarships. Students will be required to enter the service of the company during vacation periods.

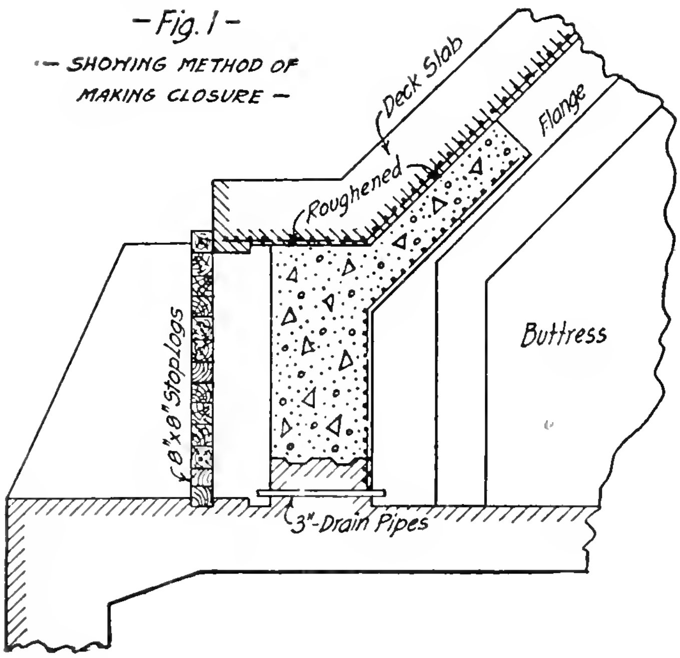
REINFORCED CONCRETE HOLLOW DAM OF BUTTRESS TYPE.

By J. K. Finch and W. F. Thoman.

Concrete-steel is a relatively new material and the design of structures involving its use has not yet reached that state of standardization which exists, for example, in structural steel work. Certain tables and rules have been devised but in the details of design much is left to the ingenuity and practical skill of the designer. The nature of the material and its method of fabrication are almost entirely responsible for this. The manufacture of steel is carried out in a shop under ideal conditions for fabrication and inspection, and its erection is merely a matter of assembling and putting together the various units that go to make up the structure. Reinforced concrete, on the other hand, is manufactured in place, in the field, sometimes under far more ideal conditions, and by labor that is, for the most part, unskilled. Its supervision should always be in the hands of experienced and competent men. Unfortunately, this is not always the case and oftentimes the caliber of the construction organization will have considerable influence in determining the details of design.

- Fig. 1 -

— SHOWING METHOD OF MAKING CLOSURE —



The forms, or molds, for the concrete exert even a greater influence. The cost of the forms is usually from one-half to two-thirds of the entire labor cost in a concrete structure, and very often economy of materials must be sacrificed to the simplification of the form work. As a general rule, all details should be made as simple as possible. Where the erection is to be beyond the control or supervision of the designer, great caution should be exercised in designing and delineating small but important details which may appear unimportant to the man in the field. The monolithic character of concrete will also introduce stresses due to continuity which may sometimes be used to advantage, but must always be provided for. Contraction and expansion must also be taken care of by the designer and not left to the ingenuity of the erector.

In this and the following papers, the notation, formulæ, unit stresses, etc., recommended by the Joint Committee on Reinforced Concrete will be mainly followed.*

* Proceedings, Am. Soc. C.E., February, 1913, p. 117.

Four or five types of hollow concrete dams have been developed, but the most widely used and the original form is the buttress type, which is here discussed. This form is patented by the Ambursen Hydraulic Construction Company, Limited, of Boston, Mass.

The first dam of this kind was built at Theresa, N.Y., in 1903, and was designed by Messrs. Ambursen and Sayles, of Watertown, N.Y. Since that time, over 75 dams have been built, varying in height up to 150 feet and in length up to 1,200 feet.

It is not the purpose of this paper to discuss at any length the merits of this type but a brief summary of its advantages seems desirable.

Compared with the regular gravity section of stone or cyclopean masonry we note that the latter is usually designed in such a way that the resultant pressure on the base acts at or near the down-stream edge of its middle third. Here the water pressure is turned downward by the weight of the masonry alone, and it is readily seen that an increase in head on such a dam will cause the resultant to pass outside the middle third, producing tension at the upper toe and finally overturning the structure if it does not fail in some other way before this occurs. In the hollow type the inclined slab causes the water pressure to be directed downward at all times, and the resultant pressure can be made to cut the base at any desired point by varying the design.

The facility with which the base pressure may be reduced in intensity by spreading the base, and made uniform over the base by correct proportioning is one of the marked advantages of this type of dam. In some cases, where the river bed is a hardpan or cemented gravel, overlying impermeable strata, the dam may be built directly on this material, because of this fact, and no deep foundations need be used. Extreme caution should be exercised in using this form of construction, however, and in general the buttresses should rest on rock or its equivalent, and the cut-off wall should extend to impermeable strata below all possible underflow.

The danger of ice thrust is also eliminated, as an ice jam would be forced up the inclined slab and its weight distributed over the structure, or, if the water were high enough, would be forced over the top of the dam.

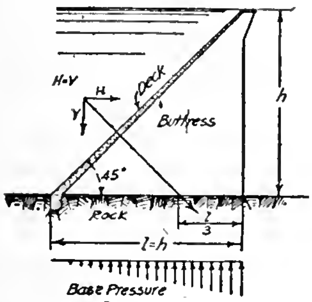
While the hollow dam will, in general, cost less than a masonry structure of the gravity type, and while there are many places where the easy control of base pressure in the former makes it available because the cost of the latter would be prohibitive, no fixed cost relation can be given. Reinforced concrete work requires steel and lumber, the cost of which may, in some localities, be excessive, making a gravity dam more economical.

No actual failures have been recorded, but the oldest dam has been in service only 10 years. Cases have occurred in which the foundation has washed out under the dam, which has arched over the opening and remained practically intact. These serve to emphasize very forcibly the necessity of having the cut-off wall extend to a sufficient depth. It should also be remembered that the strength of the structure depends primarily on the imbedded steel, which must therefore be fully protected from rust. This can be done only by proper allowance for temperature cracks, by the use of expansion joints, and by using a concrete which will be essentially watertight.

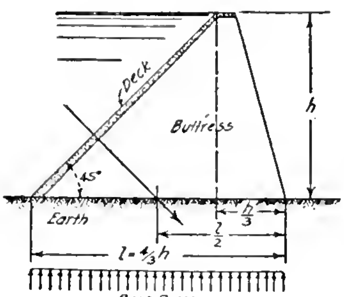
Spillway.—Several types have been developed, depending on the head and on the foundation material. On ledge rock, a spillway section with a complete or part rollway is used when the fall exceeds 10 feet or thereabouts, depending on the quality of the rock surface and its ability to withstand the force of the falling water. On soft material, either a

water cushion must be formed for low heads, possibly by slightly extending the base of the dam and placing a small barrier dam at its downstream edge, or a complete rollway, with or without an apron to prevent scour, must be used.

Construction.—The usual method is similar to that employed in the construction of masonry dams, but the required cofferdam is usually far less costly and of a more temporary character. The foundation and lower sections of the bulkhead are first constructed, and the entire flow of the stream is allowed to pass through this partially completed section while the upper parts of the buttress and slab are being erected and the remaining portions of the dam completed. The final closure is usually made as shown in Fig. 1, without employing any expensive cofferdam. This method is patented. The procedure in the erection, field joints, and forms will be discussed further on.



- Fig. 2 -



- Fig. 3 -

Slope of Deck and Shape of Buttress.—The deck slope is generally made 45 deg. The reason for this becomes clear by reference to Figs. 2 and 3. Fig. 2 represents a dam on a rock foundation where the resultant base pressure may be allowed to take the triangular form, i.e., the resultant may cut the base at or inside the middle third. This result must be obtained at the least cost. Neglecting the weight of the dam itself, and drawing the buttress with a vertical downstream face, which will evidently be the minimum practical form, it may be easily shown that a 45 deg. slope for the deck just satisfies this condition. A steeper slope would result in a little saving in the deck but would require an addition to the buttress on the downstream side to keep the resultant within the required limit. A greater slope would result in an increased slab and buttress. The relation, base equals height, therefore represents the economical proportions for this type of dam on a rock foundation.

On some foundations it is evident that it will be advantageous to have a practically uniform distribution of loading over the base. A brief consideration will show that this can best be obtained by applying an additional downstream section to the buttress, as shown in Fig. 3, giving a total bottom width equal to 1⅓ h. The uniform distribution of pressure could have been obtained, it is true, by decreasing the slope of the deck, but this would result in increasing the vertical component of the resultant water pressure and thus also the intensity of the base pressure, a condition not desired. It is therefore clear that the slope of the deck may be made 40 deg. for all conditions and, in softer material, the buttress may be given a downstream slope of between 0.25 and 0.33 of its height; this will bring the centre of pressure about the centre of the base, when the weight of the dam is considered in conjunction with the vertical component of the water pressure.

The top width of the buttress may be zero, but will generally be made 3 or 4 feet, to provide additional strength for ice thrust, where such is liable to occur, or to carry a walk across the top of the dam to facilitate inspection, etc. Where no ice is expected the walk may be carried on brackets, as shown in Fig. 2.

Buttress Thickness.—The buttress may have a tapering section, varying from a minimum thickness of 12 in. at the top to dimensions determined by the allowable pressure on the concrete, and shear at the different depths. The tapered section is, however, not so advantageous from the constructor's standpoint as a vertical section, increasing by offsets at intervals of 10 or 12 ft.; this plan offers a support for the bottom of the forms for each "lift." The minimum section should therefore be of 12-in. thickness for not over 10 or 12 ft., and should be increased in thickness 2 in. for each additional 10 or 12 ft. of depth, or as required by the working stresses in the concrete. A 1:3:6 concrete is commonly used for the buttresses, the allowable compression on which may be taken at 300 lb. and direct shear at 75 lb. per sq. inch.

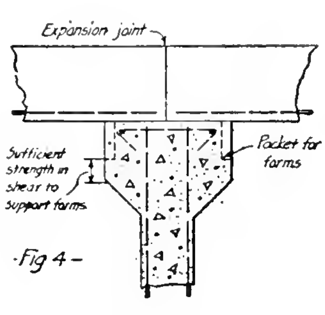
Struts.—These should be introduced at suitable points to brace the buttresses transversely. They should be placed a distance apart not over 15 times the thickness of the buttress and, to facilitate construction, should be placed at the levels where the offsets in the buttress occur. Their least dimension should not be less than 1/15 the distance between buttresses, and they should be reinforced to act as columns and carry their own weight as beams.

Spacing of Buttresses.—This will usually be between 14 and 18 ft., depending on the height and unit costs. As the distance, centre to centre of the buttresses is decreased, the span of the deck slab is decreased, and hence a saving in its cost results. More buttresses will be required, however. It is therefore clear that there must be some spacing which results in the greatest economy.

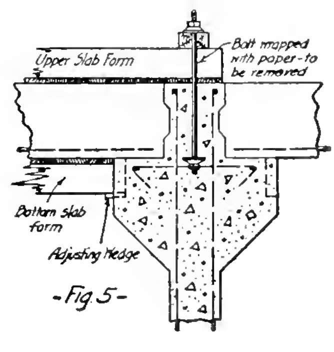
This economical spacing may be determined by the formula:

$$l^3 = \frac{370 + 17.5\,h}{\sqrt{\frac{h}{2}}}$$

in which h represents the average head and l is the spacing of buttresses. This formula can be readily derived by finding the volume of concrete and steel, and the area of form



- Fig. 4 -



- Fig. 5 -

work in the deck, buttresses and foundations in terms of h and l; applying to the same certain assumed unit prices and taking the first derivative of the total cost with respect to l. By equating this result to zero the value of l as above is found to satisfy the conditions of minimum cost under the units assumed. The unit prices will, of course, vary with local conditions but it will be found upon analysis of the formula that even under considerable variation in the unit prices the value of l will not change much. The prices assumed in this case include only the items affected by a variation in the buttress spacing, and were as follows:

Concrete in deck	14.0c. per cu. ft.
Concrete in buttress and foundation	12.0c. per cu. ft.
Steel in deck and foundation	1.9c. per lb.
Steel in buttress	2.0c. per lb.
Forms (labor only)	10.0c. per sq. ft.

Substituting in the above equation the average value of h, which is 18 ft. for the design hereafter considered, gives the economical spacing of 15 ft., which has been used.

Buttress Flanges.—Two methods are available for making the connection between buttresses and adjoining slabs. A continuous slab over the buttress would not be used, as expansion joints will be placed here to prevent cracks from forming in the deck. This point has already been discussed, and is of vital importance.

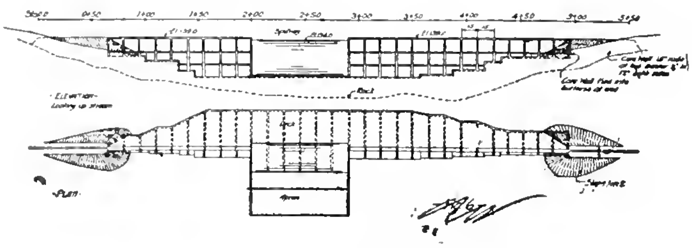


Fig. 6.

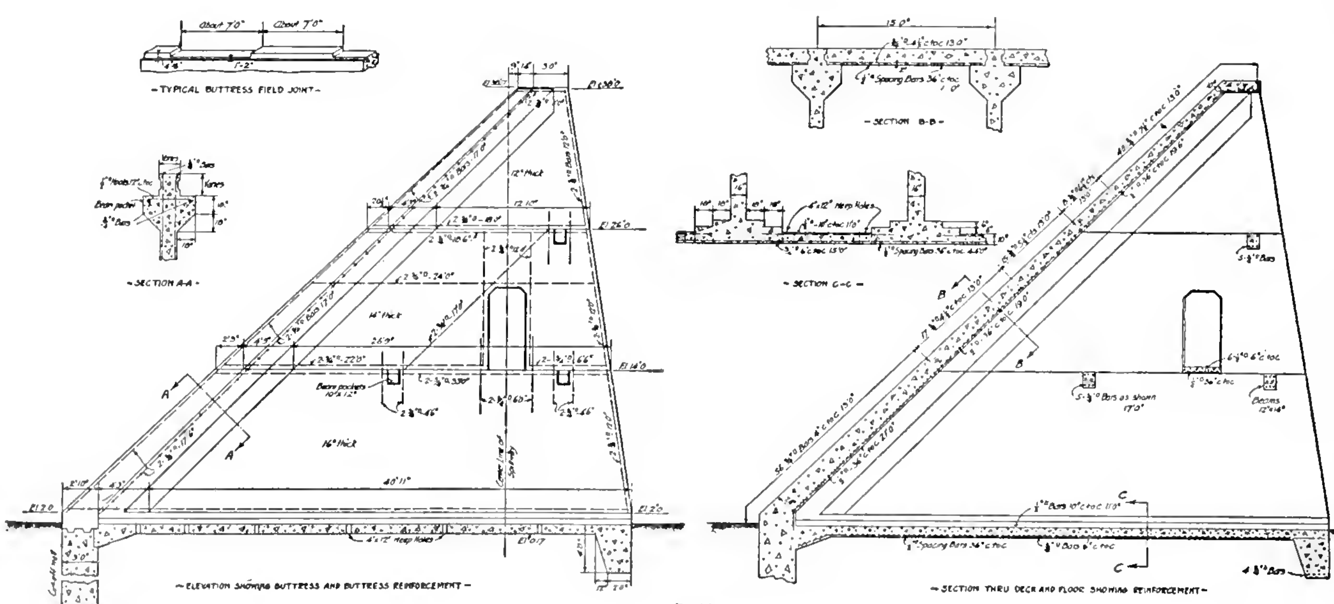
The type of joint shown in Fig. 4 is evidently very simple and would doubtless be preferred by some engineers, as it would be less costly than that shown in Fig. 5. The latter possesses some important advantages, however. Thus, the joints for expansion are doubled. The projecting portion between the slabs is cast with the buttress and not only furnishes lateral stability to the buttress from the slabs, but also furnishes a support for the top slab form and acts as a bulkhead when the slab is cast, thus saving this troublesome detail. It enables a bolt to be set in, as shown, to hold the outside form for the slab, said bolt being removed with the forms without leaving any hole through the slab. The slab span is also shortened by the greater projection of the flanges, and its cost is reduced, while the large mass of concrete thus concentrated in the flanges adds greatly to the stability of the structure.

The design of these flanges is largely a matter of judgment. It has been shown by tests of simply supported beams, with straight horizontal rods, that the length of support (overhang of the bracket or flange) must be greater than that required simply to keep the bearing pressure within reasonable limits, or the beam will fail in bond at the ends. It may also be shown by a simple computation involving the increase of concrete and steel in the projection, and the corresponding saving in the concrete and steel of the slab, that for economy the average projection may generally be made about equal to the average slab thickness.

If we attack the problem in another manner, that is, by computing the thickness required for shear, we shall generally arrive at about the same figures. Thus recent tests[1] have shown that a plain concrete bracket will take an ultimate shear of about 100 lb. per sq. in. on the section where it joins the buttress. The same tests prove conclusively that the hook form of reinforcement, such as is shown in the design herewith given, is the most efficient form and that brackets so reinforced may take as high as 400 lb. per sq. in. ultimate shear. It would therefore appear to be reasonable to compute the flange for, say, 40 to 60 lb. per sq. in. The slope of the bracket outward from the buttress certainly should not be made greater than 45 deg. and the minimum thickness of the flange at the outer edge must be sufficient to give a bearing with the required strength in shear for the ends of the beams which support the form for the bottom of the deck slab, as shown in Fig. 5. All these points must therefore receive due consideration in designing this important detail.

The flange may, of course, be decreased in size toward the top of the buttress, and this would be done in very high dams. In dams of moderate height, however, it will be seen that economy in forms makes it desirable to keep the projection the same throughout, and simply cut down the depth or thickness. This can be easily done, using the same forms throughout, if they are properly designed. In the design hereafter considered, the same projection is used throughout.



- Fig 7 -

The size of reinforcing rods is largely a matter of judgment. Tests show that the best form is the horizontal hook. Two vertical rods are run down the flanges and the smaller transverse bars are hooked over them. These hooks and rods serve the double purpose of reinforcing the projection

[1] Concrete-Cement Age, February, 1913, p. 68.

as a cantilever, and also in aiding to take up any tension in the direction of the slab, due to the friction between the slab and the bracket, which may occur if the slab contracts.

Deck.—The thickness of the deck slab should not be less than 10 in. at the top, to allow space for properly placing and tamping the concrete on the deck. This concrete should be a rich, dense mixture, usually 1:2:4, and should be mixed wet to insure the filling of all voids and the thorough coating and protection of the rods.

It will generally be found that if the thickness is assumed as 10 in. at the top, and is computed at the bottom of the buttress, that a straight line between these points will give a sufficient thickness at any depth. A change in deck slope at each lift may be made without any difficulty, so that economy will result if the thickness is computed at these points and the slope made uniform between them.

Slab Formulas.—The following formulas may be easily deduced from the thickness of the slab and the required amount of steel for bending at any depth.

Let w = weight of any liquid in lb. per cu. ft.
x = depth of liquid on slab in ft.
l = span of slab in ft.

Then the bending moment in the slab $= wxl^2 \div 8$ for a non-continuous slab, and with water at 62.5 lb. per cu. ft. $M = 7.818xl^2$. But from formula for reinforced slabs, $M = Cbd^2$, and we have $d = \sqrt{\dfrac{7.818xl^2}{Cb}}$ .... (a)

For a 1:2:4 concrete, with $n = 15$, $f_c = 600$ and $f_s = 14{,}000$ lb. per sq. in., $C = 8.50$ ft. lb. and $b = 12$ in. for a slab. Hence in non-continuous beams, d in inches $= 0.277\, l \sqrt{x}$ .... (b)

Also from the formula $A_s = \dfrac{M}{f_s jd}$ we have $A_s = \dfrac{7.818xl^2}{f_s jd}$ per ft. width of slab, where A_s is in square inches. Now the spacing of the bars in inches to obtain this area is $S = 12 \times$ area of one bar $\div A_s$. Hence the spacing at any depth is:

$$S = \frac{12 \times \text{area of one bar} \times f_s jd}{7.818xl^2} = K\frac{d}{x} \text{ .... (c)}$$

where K is a constant when the size of the bars to use has been decided on, the other quantities being known.

The shear, as a measure of diagonal tension, may generally be taken at a somewhat higher figure than customary as the slab will be so thick in proportion to its span at the depth where the shear is high that considerable arching will occur. Taking this figure at 60 lb. per sq. in. we find: Reaction per inch of slab

$$= \frac{62.5lx}{2 \times 12} = \tfrac{7}{8} \times 60d = \tfrac{7}{8} \times 60 \times 0.277\, l\sqrt{x}$$

giving $x = 31$ ft.; that is, when the height of dam exceeds 31 ft. the shear in the slab neer the buttresses becomes the limiting factor. As the depth increases a slab of arched section may be used, giving a sufficient thickness of concrete at the ends that the shear will not exceed 60 lb. per sq. in., and the required steel is introduced for bending. An increase in the strength of slab to resist diagonal tension could, of course, be obtained by using stirrups. This would permit a shear up to 120 lb. but it would be very difficult, if not impossible, to place the stirrups properly in constructing the slab, hence this method is not used.

Foundation.—On firm ledge rock no spread footing may be necessary, but on softer rock a stepped-out footing can be used. By varying the width of footing the unit pressure may be made almost uniform, even with a buttress of the shape shown in Fig. 2. In some cases, the bases of the buttresses are stepped out, the thickness and amount of steel being computed, with due allowance to shear and bending, on the assumption that the spread acts as a cantilever, and the remaining space between buttresses covered with a reinforced floor which is computed as a continuous beam supported by the cantilever footings. Weep holes are placed at intervals throughout the base to prevent upward water pressure on it.

The angle of the resultant pressure on the base should also be investigated, and proper precautions taken to prevent sliding of the dam.

Spillway.—The length, elevation, and depth of probable flood flow having been decided on, it remains to take care of this flow so that no damage will result to the structure. The following formula has been used in designing the curve for the upper part of the spillway.[3]

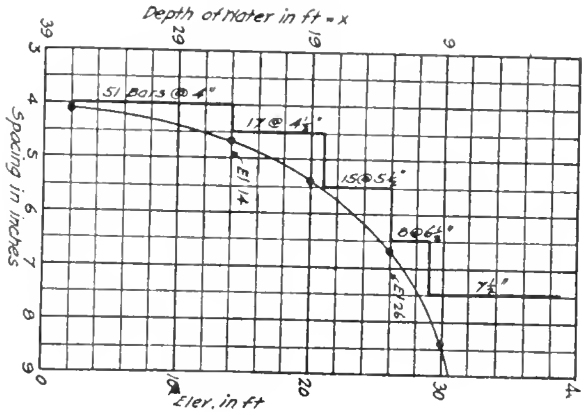


Fig. 8.

$$x^2 = 2.3 \times H \times y \text{ .... (d)}$$

Where x = the offset in feet.
y = the distance below crest in feet.
H = depth of flood flow in feet.

It is believed that this equation gives a spillway curve such that the overflowing water will adhere to the spillway surface and no vacuum effect will be possible. In order to guard against this, however, vent pipes are introduced in each bay, as shown in the accompanying drawing.

No satisfactory method seems to have been developed for designing the lower curve of the ogee section. In the design given this curve has been made the reverse of the top curve, which seems to be a safe procedure.

The design of the curved spillway slab is essentially a matter of judgment, the thickness and reinforcing depending on the expected flood flow and the possibility of logs, ice, etc., being carried over the dam.

General Conditions.—The general layout and profile are shown in Fig. 6. The conditions for the design are as follows:—

In order to illustrate the method followed in such a design, the river bed will be assumed as hardpan and the conditions such that the dam may be built on a spread foundation resting directly on the river bottom, provided the foundation pressure is made uniform and at an intensity not to exceed 2 tons per sq. ft. A full rollway section for the spillway, with downstream apron to prevent scour, is also desirable.

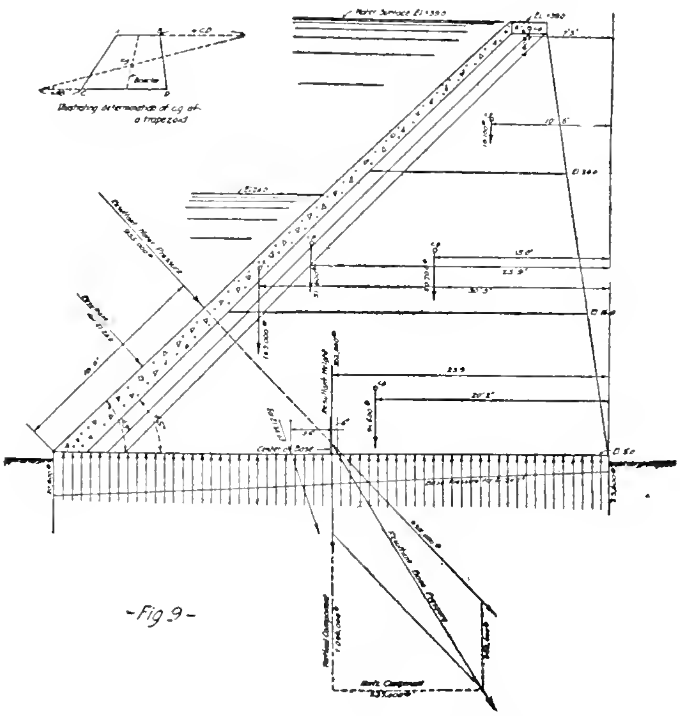
---

[3] Eng. Rec., October 24, 1908, p. 461.

Elevation of crest of spillway will be taken at + 36 ft.; maximum flood height 37.5 ft.; and crest of dam + 39 ft., making an allowance for waves, etc., of 1.5 ft. Dam will be designed for a head of water equal to the full height of dam and the spillway to pass a 3-ft. flood.

Unit stresses in lb. per sq. in.

	Deck and apron.	Buttress.	Footing.
Mixture	1:2:4	1:3:6	1:3:6
Concrete in compression	600 (bending)	300 (direct)	500 (bending)
Concrete in shear (direct)	—	75	75
Concrete in shear (diag. tension)	60	—	40
Steel in tension	14,000	—	14,000



-Fig. 9-

The section at greatest depth only will be designed. For other depths, a similar section is used, the floor system being stepped up, as shown in Fig. 6, with step-up walls designed to assist the lateral earth pressure, and provided with pipe drains to prevent the possibility of water pressure.

Buttresses.—Width of base will be made about 0.3 greater than height (37 ft.) or 48 ft. Top width for walk, 3 ft. Built in three lifts of 12 ft., and thickness of 12, 14, and 16 in., as shown on Fig. 7. Reinforcing bars will be placed as shown to tie the buttress together, as it has been found from experience that they are necessary to prevent cracks. Struts will be used as shown, and door openings left in each buttress, with connecting slab, forming a passageway entirely through the dam.

Buttress flanges will be made with an overhang of 18 in. or about equal to the depth of slab. This is a little over the economical amount but inasmuch as it will be found later that the minimum thickness of the outer edge of the overhang must be about 16 in. in order to support the forms, this figure will be used, as it gives a proper proportioning. As a check, the shear should be computed at the centre of the flange, using about 50 lb. per sq. in. This will be found to check closely with the design given. The same forms will be used throughout, so the overhang will remain constant.

Slab.—Using a minimum of 10 in. at the top, the required thickness at elevations 2.0, 14.0, and 26.0 are computed by equation (b) and found to be 22, 19 and 14½ in. respectively, allowing 2 in. for protection. At elevation 2.0, however, the depth is 37 ft.; hence the shear, as a measure of diagonal tension, will control. This may be taken at 60 lb. per sq. in., a high value, which is permissible because the slab is so deep in comparison to its span that arching will doubtless occur. Hence

$$d = \frac{62.5 \times 12.16 \times 37}{2 \times 12 \times 60 \times \frac{7}{8}} = 22 \text{ in.} + \text{protection} = 24 \text{ in.}$$

and the slab will be made 24 in. thick.

The steel may now be computed from equation (c) which reduces to $S = 6.95\,d \div x$ if we use ¾-in. square bars. These bars are used as they will give a reasonable spacing (4 in.) at the bottom of the slab and may be used throughout with very little waste. It is a poor plan to use bars of different sizes in the deck, as there is a possibility of the bars being placed incorrectly. It is also preferable to make the change in spacing at the lift levels where the forms will be changed.

At el. 2	effective depth = 22 in.	x = 37 ft.	and S = 4.1 in.
" " 14	" " = 17.0 "	= 25 "	= 4.7 "
" " 20	" " = 14.75 "	= 19 "	= 5.4 "
" " 26	" " = 12.5 "	= 13 "	= 6.7 "
" " 32	" " = 12.25 "	= 7 "	= 12.0 "

Plotting these results we obtain the curve shown in Fig. 8, from which the spacing of the bars is taken as indicated.

Spacing bars ½ in. square, 36 in. on centres, will be used throughout the slab to hold and secure the reinforcing bars at the proper spacing, and will be lapped 2 ft. into each "lift" of the slab to tie the sections together.

It now remains to check the buttress design for shear and compression, determine the foundation pressure and design the footings.

The horizontal water pressures may be found from the formula $wx^2 \div 2$, which amounts, divided by the area of the buttress section at elevations 26.0, 14.0, and 2.0, give 22, 44 and 61 lb. per sq. in. respectively, which stresses are within the allowable.

Foundation Pressure.—Fig. 9 shows the graphical construction for determining the base pressure. The weights of the slab, flanges, and sections of the buttress are first computed, allowing 150 lb. per cu. ft. for the concrete. The centre of gravity of each section is then determined as shown, and the line of action of the entire weight of the dam is determined by taking moments about the toe. Thus:

	Weight.		Moment about toe.
Walk	6,800 lb.	× 7.25 =	49,000
Top lift buttress	18,100 "	× 10.5 =	190,000
Middle lift buttress	50,700 "	× 15.0 =	760,000
Bottom lift buttress	91,600 "	× 20.17 =	1,840,000
Slab	163,200 "	× 30.25 =	4,950,000
Flanges	51,600 "	× 25.75 =	1,328,000
Total	382,000 "	Tl. moment =	9,117,000

Distance from lower toe to line of action = 9,117,000 ÷ 382,000 = 23.9 ft.

The resultant water pressure per bay, which acts one-third up the inclined slab and at right angles thereto, (note that the slope of the front face of slab is about 43°) is found

$$\text{to be } \frac{62.5 \times 37}{2} \times 54 \times 15 = 935{,}000 \text{ lb.}$$

Combining this with the total weight of dam, as shown, the resultant is found to cut the base 0.5 ft. downstream from the centre. The total weight of dam plus 935,000 × cos 43° (or 684,000 lb., the vertical component of the water pressure) gives the total normal pressure on the base of 1,066,000 lb. Using the well-known formula,[1]

$$p = \frac{P}{l}\left(1 \pm \frac{6b}{l}\right)$$

where p = pressure on base in lb. per lin. ft.
P = total vertical load in lb.
l = length of base in ft.
b = distance resultant pressure to centre of base in ft.

we get an equivalent uniform load of 22,200 lb. per lin. ft. and p (max.) = 23,600 and p (min.) = 20,800 lb. per lin. foot.

As the width of buttress is 16 in. this represents a maximum compressive stress on the buttress of 23,600 ÷ (12 × 16) = 123 lb. per sq. in., which is entirely satisfactory. A similar computation for elevations 14.0 and 26.0 will also give results well within the limit of 300 lb. allowed.

The resulting pressure on the base with the water level at elevation 24.0 is also shown.

Footings.—A cross-section of the footing is shown in Fig. 7. It is designed as a simple cantilever footing having a width sufficient to transmit the load from the buttress to the soil at a reasonable unit foundation pressure. Thus, if we assume the width of cantilever as 10.5 ft. the load will be 2,250 lb. per sq. ft. The exact distribution of the foundation pressure is indeterminate and the unit pressure directly under the footing will probably be in excess of the above figure, but it is thought that this represents a safe design for the footing. The thickness of the cantilever next to the buttress will be controlled by shear, which may be taken at 50 lb. per sq. in., giving a required thickness of 2,250 × 4.58 ÷ 12 × ⅞ × 50 = 19½ + 2½ in. protection = 22 in.

The bending moment will be

M = (2,250 × 4.58 × 4.58) ÷ 2 = 23,600 ft. lbs.

From the formula $A = M \div f_s jd$; with $f_s = 14{,}000$, $f_c = 500$, $n = 15$, we have $j = 0.864$ and

$$A_s = \frac{M}{1030d} = \frac{23{,}600}{1030 \times 19\frac{1}{2}} = 1.17 \text{ sq. in. per ft.}$$

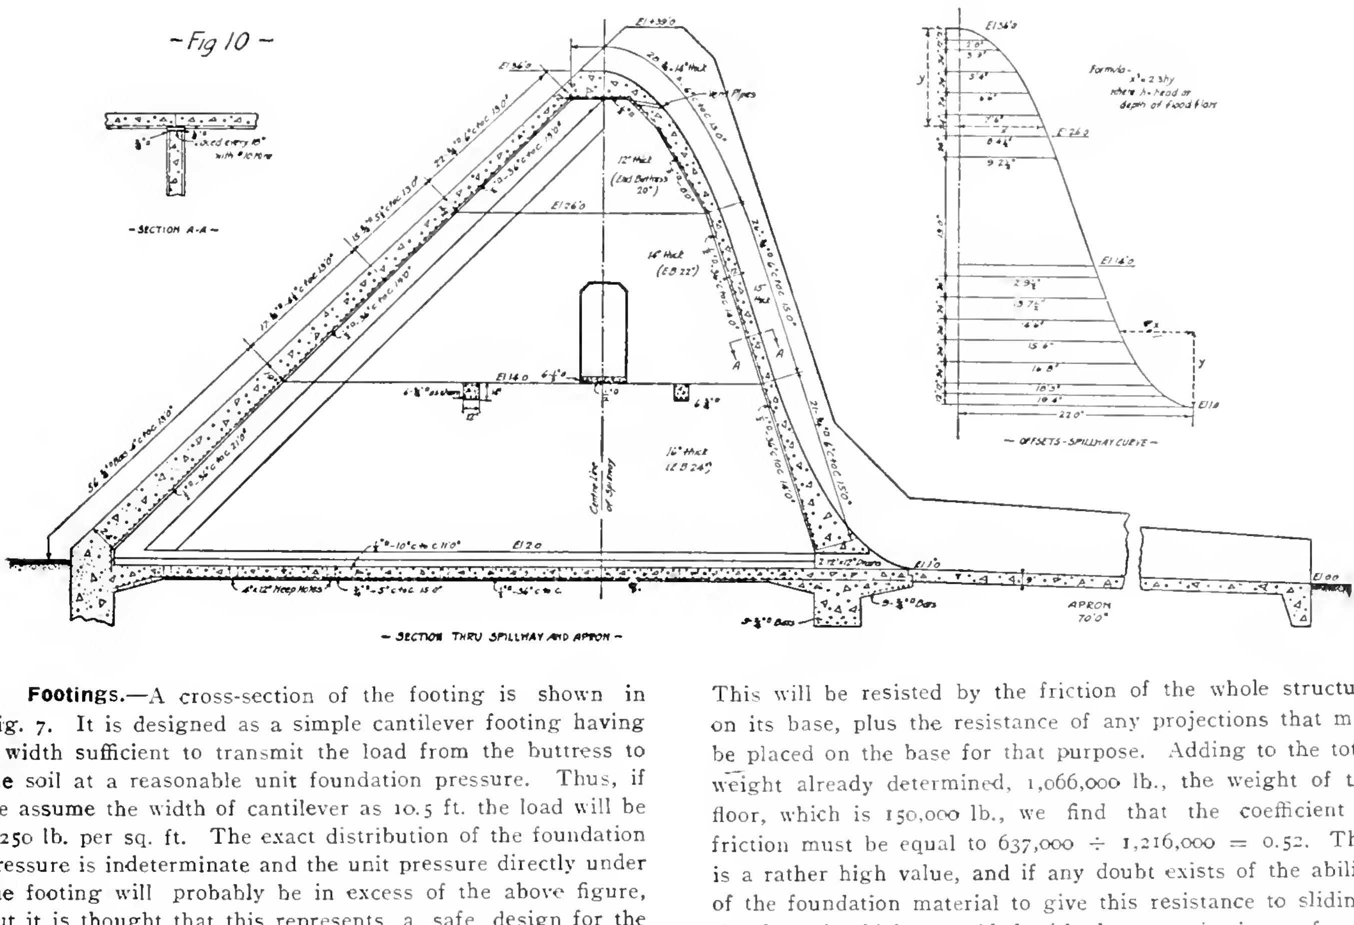
or ¾ in. square bars, 6 in. centre to centre, will be required.

The points where the raises in the footing may be made so that the shear may not exceed 50 lb. can be found by drawing a line from the edge of the buttress at the top of the footing to the centre of steel at the edge of the cantilever. This gives a convenient raise of 6 in. with an offset of 18 inches.

The slab covering the space between the ends of the footings will be computed as a continuous beam with a span of 15 — 10.5 = 4.5 ft. The maximum load that could come on this slab would occur on the assumption that the foundation load is uniformly distributed over the entire foundation. This assumption would give a load of 23,600 ÷ 15 = 1,570 lb. per sq. ft., and the bending moment in the slab would be M = (1,570 × 4½ × 4½) ÷ 12 = 2,650 ft. lb., requiring an area of steel A_s = 2,650 ÷ (1,030 × 8½) = 0.30 sq. in. per ft., which can be obtained by using ½-in. square bars 10 in. centre to centre.

Stability Against Sliding.—The horizontal component of the water pressure will be 935,000 × sin 43° = 637,000 lb. This will be resisted by the friction of the whole structure on its base, plus the resistance of any projections that may be placed on the base for that purpose. Adding to the total weight already determined, 1,066,000 lb., the weight of the floor, which is 150,000 lb., we find that the coefficient of friction must be equal to 637,000 ÷ 1,216,000 = 0.52. This is a rather high value, and if any doubt exists of the ability of the foundation material to give this resistance to sliding, the dam should be provided with base projections of sufficient size to resist the unbalanced thrust. The 4-ft. cutoff wall, shown in Fig. 10 at the downstream toe, will aid in resisting sliding, but should not be counted on to do so as its function is simply to prevent possible backwash from undermining the floor.

Spillway.—The spillway design is given in Fig. 10. The formula used to compute the spillway curve has already been stated and it was also stated that the design of the rollway slab was largely a matter of judgment. The other features



[1] See Baker's "Masonry Construction," p. 473.

of the design are identical with those already discussed, and no further computations will be made.

Forms.—Wall forms will be built in panels, as shown, the area of the panel being determined by the fact that, even where derricks and cable-ways are available, conditions frequently arise that require the manhandling of forms; hence they must be within the lifting capacity of the number of men that can be conveniently grouped around them for that purpose. For this reason no form will exceed 800 lb. in weight.

All forms will be designed to resist the loadings due to pressure of water in the concrete for the full heights of each lift.

Stresses used will be based upon the ultimate unit stresses recommended by the Association of Railway Superintendents with a safety factor of three, which is ample for temporary work of this character.

INTERNATIONAL ENGINEERING CONGRESS, 1915.

In connection with the Panama-Pacific International Exhibition which will be held in San Francisco in 1915, there will be an International Engineering Congress, in which engineers throughout the world will be invited to participate.

The congress is to be conducted under the auspices of the following five national Engineering Societies: American Society of Civil Engineers, American Institute of Mining Engineers, The American Society of Mechanical Engineers, American Institute of Electrical Engineers, and The Society of Naval Architects and Marine Engineers.

These societies, acting in co-operation, have appointed a permanent committee of management, consisting of the presidents and secretaries of each of these societies, and eighteen members resident in San Francisco.

The committee has effected a permanent organization, with Prof. Wm. F. Durand as chairman, and W. A. Cattell as secretary-treasurer, and has established executive offices in the Foxcroft Building, 68 Post Street, San Francisco.

The ten members of the committee, consisting of the the presidents and secretaries of the five national societies, will constitute a committee on participation, through whom all invitations to participate in the congress will be issued to governments, engineering societies, and individuals.

The honorary officers of the congress will consist of a president and a number of vice-presidents selected from among the most distinguished engineers of this and foreign countries.

The papers presented at the congress will naturally be divided into groups or sections. During the congress each section will hold independent sessions, which will be presided over by a chairman eminent in the branches of engineering covered by his section.

The scope of the congress has not as yet been definitely determined, but it is hoped to make it widely representative of the best engineering practice throughout the world, and it is intended that the papers, discussions and proceedings shall constitute an adequate review of the progress made during the past decade and an authoritative presentation of the latest developments and most approved practices in the various branches of engineering work.

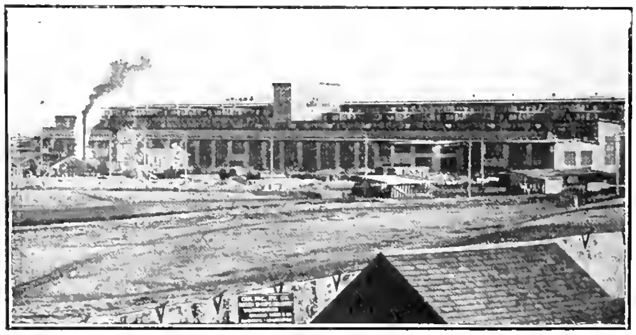
The papers, which will be collected and published by the congress, should form an invaluable engineering library, and it is intended that this publication shall be in such form and at such cost as to become available to the greatest possible number.

CANADIAN PACIFIC RAILWAY SHOPS AT OGDEN, ALBERTA.

The Canadian Pacific Railway has recently put in operation near Calgary, Canada, a large shop plant of more than ordinary interest by reason of its size, its complete and modern character, and the speed with which it was created.

The work was designed and built in its entirety by Westinghouse. Church, Kerr & Company, consulting and constructing engineers, of Montreal and New York, working under the direction of Mr. J. G. Sullivan, chief engineer of the western lines of the Canadian Pacific Railway, and Mr. N. E. Brooks, divisional engineer.

The shop location is at Ogden (named in honor of a vice-president of the railway), and is 4½ miles from Calgary and about 2,250 miles from Montreal. Its distance from those sections of the country where the greater part of the construction materials, machinery and equipment were produced constituted the first and one of the most important problems. A second important problem arose on account of the construction season being extremely short, owing to the high latitude, frost remaining in the ground until about April 1st and returning with snow as early as October 1st. A third very important problem was the comparative scarcity of labor in the Canadian North-West, this condition being greatly aggravated during the late summer months, when harvesting begins and all labor markets are practically drained of men.



Main Building From West, Showing Blacksmith and Boiler Shop Bays.

Plans had, therefore, to be drawn, materials ordered, deliveries made and complete field organization perfected so that the shops could be closed in between April and December 1st, and sufficiently heated so that inside work could be continued after cold weather had set in. How this was done will be seen by the following progress diagram:—

The shops consist in general of:—

Main locomotive shop (including erecting, machine, blacksmith and boiler shops).

Tender and wheel shop.

Pattern shop and pattern storage.

Foundry.

Storehouse and office building.

Material platforms and scrap docks.

Oil-house.

Carriage repair and paint shop.

Freight car repair shop.

Planing mill.

Boiler-house.

1,260-foot yard crane.

Miscellaneous structures, including transfer table and pit for coach shop, main hoist, wells, and water-tower, and all service systems, such as drainage, sewers, fire protection, water supply, etc.

Main Locomotive Shop.—This building is designed to contain the erecting shop, machine shop, blacksmith shop, and boiler shop.

The erecting shop is of a transverse lift-over type, and contains thirty-five bays, each twenty-five feet between centres, and is 778 feet long by 75 feet wide. The entire area is served by two travelling electric cranes, carried on two levels. The 120-ton crane, furnished with two 50-ton trolleys, is carried on the upper level, and is used for transferring, wheeling and unwheeling locomotives and handling parts. One of the trolleys on this crane is equipped with a ten-ton auxiliary hoist for handling light material at a high hoisting speed.

Another ten-ton travelling electric crane operates at high speed, and serve the entire area of the erecting shop for handling material in that shop and tranferring same to the blacksmith shop and machine shop. The machine shop and the boiler shop are located in adjacent bays on either side of the erecting shop.

Provision is made on the crane columns in the erecting shop for attaching portable jib cranes for use in dismantling and erecting material on the front ends of locomotives. These cranes are placed where desired by means of the overhead travelling electric cranes.

Entrance for locomotives to the erecting shop is provided through four doors, located in the west side of the shop, two of these doors being located at either end.

For providing additional means for entrance of locomotives, six door openings are provided in the east wall of the machine shop, two of these being at the north end and four at the south end.

All of these entrance tracks are connected up with the erecting pits of the several stalls where they enter the building to permit of the locomotives moving into and out of the shop through these entrances should this movement become desirable or necessary.

The machine shop to contain heavy machine tools is located parallel with and adjoining the erecting shop on one side, and is 60 feet 9 inches wide and the same length as the erecting shop. A high-speed travelling crane of ten-ton capacity covers the entire area of this shop. Material can be brought into the shop through a door provided in the end of the building the material being brought up to the end of the machine shop by the travelling electric yard crane, which travels across the end and outside of the locomotive shop.

Space for the lighter machine tools is provided in a shop 60 feet 9 inches wide parallel with and alongside of the heavy machine shop and of the same length as that shop. An overhead trolley beam is provided on the bottom chord of the roof truss to permit of using a travelling electric trolley for handling material longitudinally in this shop. Provision has been made for a foreman's office elevated above the floor and having liberal glass surface in the walls so as to give the best possible view of the shop.

The blacksmith shop is located alongside of and parallel with the erecting shop on the opposite side from the machine shop. This building consists of two bays, each 332 feet long, 60 feet 9 inches and 50 feet wide, respectively.

Space is provided for heavy forging work, steam hammers, etc., in the building immediately adjoining the erecting shop.

The blacksmith shop will not be served by a travelling crane, but provision has been made for jib cranes to handle the material from steam hammers, forgings, etc.

In a building of lower cross-section alongside are located the furnaces, bolt headers and other blacksmith shop machinery. This portion of the shop is served by a trolley its full length to facilitate the longitudinal movement of material through the shop.

The space for the boiler shop is provided in a [illegible] bay building, alongside of and parallel with the erecting shop at the end of the blacksmith shop, 352 feet long and the same width as the latter shop.

That part of the boiler shop immediately adjoining the erecting shop is provided with a 40-ton travelling electric crane equipped with two 20-ton trolleys serving the entire area of the boiler shop for handling the boilers and other material.

The riveting tower is located between two of the roof trusses in the end of the boiler shop, with a 25-ton crane for serving the hydraulic riveter.

In the outer of the two bays of the boiler shop space is provided for a flue shop and boiler shop tools. The entire length of this space is served by a 3-ton overhead travelling trolley for handling material through the shop. Space for a flue rattler is provided immediately outside of and adjacent to the low bay of the boiler shop.

An entrance track is provided through the outside wall of the boiler shop, on which boilers or other equipment going to this department can be delivered on cars under the travelling crane for unloading or may be loaded out for shipment in the same way. This facilitates the handling of boilers from steam shovels, pile-drivers, Lidgerwoods, etc.

Jib cranes are provided for serving the individual machines in the boiler shop where such service may be necessary.

Northwest View, Showing Roof Arrangements With Reference to Lighting of Erecting and Machine Shops.

The heating throughout is done by indirect fan system. For distributing the heated air underground concrete and tile ducts are used.

The general illumination consists of Cooper-Hewitt lamps, with circuit and plug boxes for extension loop cords. Provision has also been made for incandescent lighting circuits for individual lighting at machine tools where required, and for outlet boxes for connecting extension lamp cords to provide lighting for the interior of the locomotive boilers on the erecting floor.

Toilets, lavatories, and metal lockers are provided in the various departments of this shop.

A suitable system of piping is provided for distributing live steam, compressed air, fuel oil, and water for fire protection, drinking and hydraulic pressure.

Outlets for compressed air are provided in duplicate in the sides of each of the engine pits to supply compressed air for operating pneumatic tools.

In the main locomotive shop the electrical feeders from the power company's transmission lines are carried in underground ducts, bringing the current at the voltage delivered by the power company, namely, 2,200 volts, to a sub-station located adjacent to and immediately outside of the low machine bay, the transformers for stepping down to 440 volts being located in this sub-station. In this sub-

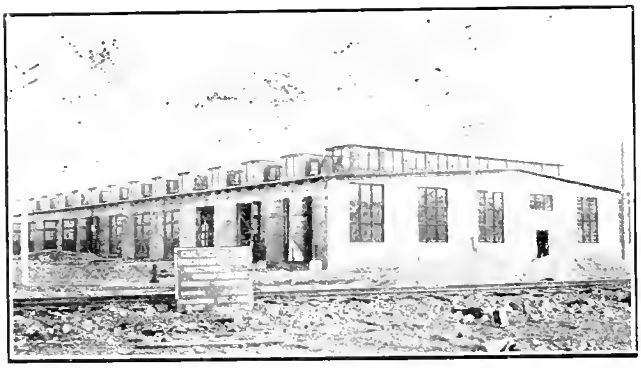
station two motor generator acts for supplying direct current are also located. The switchboard is also located in this sub-station for controlling the power and lighting circuits in the machine shop and for the tender shop and foundry. As far as possible distributing feeders are carried in conduit beneath the shop floor, thereby minimizing the amount of exposed wiring in the shops.

The building containing all of the above departments of the locomotive shop is constructed with structural steel frame carried on concrete foundations. The exterior walls up to the window-sill line are of concrete; above the window-sills of hollow tile, plastered.

Ample window area is provided in the side walls and in roof monitors and skylights so as to give sufficient natural lighting.

Good ventilation is obtained through ventilators in the monitors and skylights and by the use of swinging sash in the vertical walls.

With the exception of the blacksmith shop and a portion of the boiler shop, the floor throughout is constructed with a 1½-inch asphalt mastic wearing surface, which is underlaid with a rough concrete slab about six inches thick. In the blacksmith shop and a portion of the boiler shop the floor is of cinders.



Coach Repair Shop.

The roof sheathing is constructed of 2 x 4's, surfaced on one side and one edge and spiked together on edge, thus affording good fire-resistance qualities and materially reducing the heat losses. The roof waterproofing is four-ply tarred felt, pitch and gravel, with copper flashing. Suitable drain leaders are provided and connected into underground tiled drains to carry off the water from the roof.

The large skylight on the erecting shop bay is of steel bars, lead-covered with ribbed wired glass.

Tender and Wheel Shop.—This building is constructed with structural steel frame and with steel roof trusses, otherwise the general construction of the building is similar to that described for the main locomotive shop. It is an L-shaped structure, 263 feet by 80 feet wide, with L 180 feet long by 80 feet wide, and affords space for making repairs to locomotive tenders, steam shovels and other maintenance-of-way equipment.

That portion of the shop intended to receive the equipment to be repaired is spanned over its entire area by a 20-ton high-speed travelling electric crane equipped with two 10-ton trolleys.

Longitudinal tracks on 20-foot centres extend to the doors in the building wall.

A car-puller is installed for moving the equipment into and out of the shop.

A sufficient number of tracks extend through the rear wall of the building to facilitate the movement of material into the shop.

In the L portion of the building of lower cross section space is provided for steel tire wheel lathes, wheel and axle machinery and such other tools as are required.

A depressed track carried along the ends of the wheel storage tracks outside facilitates unloading and loading of wheels and axles.

The heating, lighting and service equipment is similar to that described for the main locomotive shop.

Pattern Shop and Pattern Storage.—Space for the pattern shop and pattern storage is provided in a separate building, located adjacent to the foundry, a fire-wall separating the pattern shop from the pattern storage.

The general construction of the building is the same as that of the other buildings—the roof of slow-burning mill construction. The structure is 162 feet long by 31 feet wide, is heated by the direct system, and lighted with keyless socket, marine type incandescent lamps. A sprinkler system is provided for fire protection.

Foundry.—The grey iron foundry building is 203 feet long by 80 feet wide, constructed with two bays. The frame is of structural steel, carried on concrete footings. The general construction is the same as that described for the other buildings, except that the floor is of the usual clay type used in foundries, and the roof over the cupola room is of corrugated asbestos.

The bay of higher cross-section is served over its entire length by a 10-ton high-speed travelling electric crane. Jib cranes, attached to building columns, are provided. These cranes are so arranged that they may be removed from one location to another if desired, being handled by the travelling electric crane. In the side bay of lower cross-section space is provided for core-making and shop moulding floor.

The charging floor for the cupola is located in the centre of the lower bay.

Heating is by the indirect fan system, with underground tile and concrete hot-air ducts. For general illumination flaming arcs are used in the high bay and ordinary arcs in the low bay, with outlet boxes for extension lamp cords.

Toilets, lavatories, and conveniences for the men are provided; also steam, air, and water service for fire protection and drinking purposes.

The location of this building alongside of and parallel with the travelling electric yard crane enables the unloading of scrap and pig-iron to be taken care of by the yard crane. This close proximity of the foundry to the yard crane also reduces to a minimum the handling of the castings from the foundry to storage, to the main shop, or in loading for shipment.

Storehouse and Office Building.—This building is 252 ft. 6 in. long by 60 ft. wide. One end of the building for a length of forty feet is carried up three stories, and contains offices on the second and third floors and a fireproof vault. The remainder of the building, for storehouse purposes, is two stories high and contains electric elevator, platform scales, material bins and shelving.

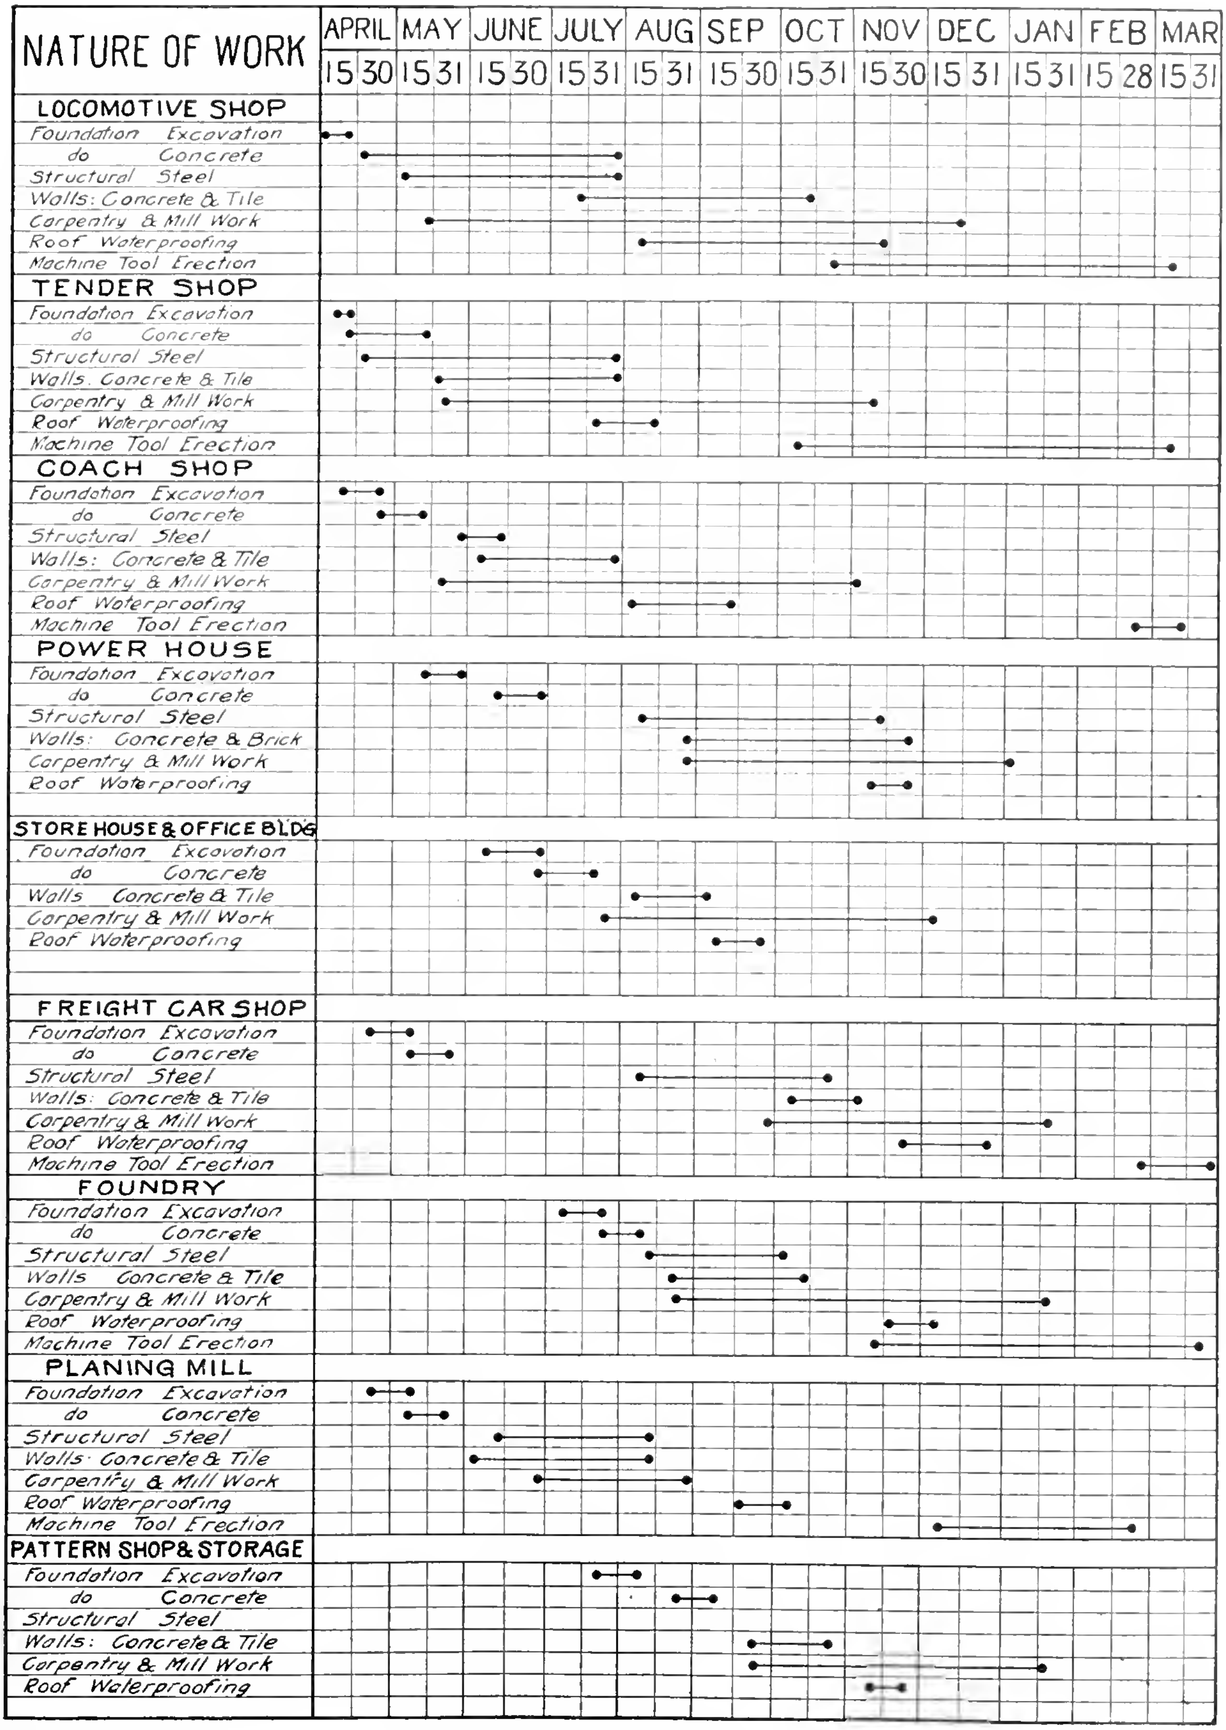
The wall are constructed of hollow-tile blocks on concrete foundations. The framing is of heavy timbers, with roof sheathing of two by fours, surfaced on one side and one edge, and spiked together on edge. The foundations are carried up to bring the floor of the storeroom to car door height.

The necessary toilet and lavatory facilities are provided. The offices are heated by direct radiation, the remainder of the building being heated by the indirect system. The lighting is by incandescent lamps. Fire protection is by automatic sprinklers.

The ground floor of the storehouse has an 1½-inch asphalt mastic wearing surface. The other floors throughout the building are of wood.

The window arrangement is such as to best accommodate the material bins and shelves without interference with good lighting.

The storehouse is located parallel with the main locomotive shop. The space between these two bu[illegible] is spanned by a high-speed travelling crane, which [illegible] be



C.P.R. Shops, Calgary—Progress Record.

utilized to handle all heavy material to and from the cars from the storage space that is provide between the storehouse and the erecting shop. The use of this crane practically eliminates manual handling of heavy material, and permits of handling numerous small parts in quantities when contained in suitable receptacles.

Interior of Planing Mill.

Material Platforms and Scrap Dock.—A material platform, 90 feet wide and about 350 feet long, abuts one end of the storehouse. This platform is also carried along either side of the storehouse, where it is 15 feet wide. It is constructed of concrete retaining walls, filled in with earth, and a topdressing of cinders covers the fill, except alongside of storehouse, where plank covering is laid. The platform extends to and along the sides of the oil-house.

Oil-house.—For storing and distributing oil a separate building is provided convenient to, but located far enough away from, the storehouse and other buildings to eliminate the fire risk. It is constructed with tile walls (plastered on the exterior) on concrete foundations, with a concrete basement at one end for the tanks which contain the oil, for local distribution. The roof is of reinforced concrete slab, as is also the floor of the pump-room over the basement. That part of the building used for storing oil in barrels has a cinder floor. The pump-room is partitioned off with a brick wall, carried up to make a fire-wall

Ten oil tanks, with measuring pumps, are installed, and provision is made for conveniently emptying the oil from barrels into the tank in the basement.

The oil-house basement is heated by the direct system to the high temperature necessary to render the oil fluid during extreme cold weather, the direct system being also used to heat the rest of the building. The lighting of the building is with keyless socket marine type incandescent lamps. Fire protection, including sprinklers, is installed.

Coach Repair and Paint Shop.—The building containing these departments is 362 feet long by 146 feet wide, having fifteen tracks on 24-inch centres. It is constructed with hollow building tile carried on concrete foundation. Heavy timber posts support the roof, which is of slow-burning mill construction. Otherwise the construction is the same as that described for the main shop building.

Space is provided along one side of the building for varnish room, upholstering, office, sub-store, paint storage, heating plant and air-brake repairs.

When necessity arises for increased shop capacity in this department it is proposed to obtain such increase by the erection of another shop on the opposite side of the transfer table.

Heating is by the indirect fan system, with underground concrete and tile ducts. Lighting is by incandescent lamps. Compressed air, steam and water service, including fire protection and automatic sprinklers, are provided Toilets, lavatories, and conveniences for the men are also supplied in this shop.

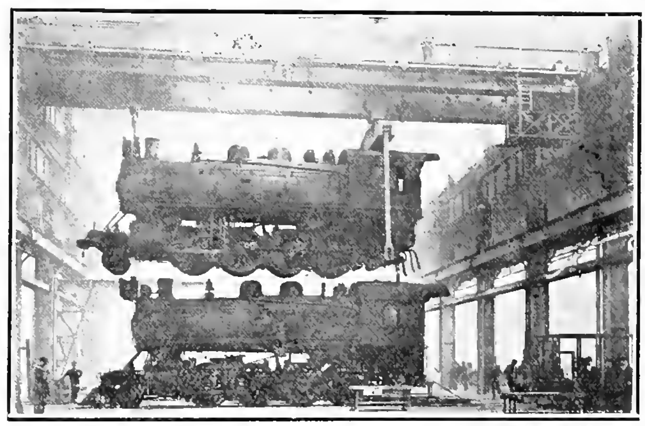
Freight Car Repair Shop.—This building is 231 feet wide by 303 feet long, and contains eight repair tracks spaced in pairs, with industrial track between each pair of repair tracks. A tile wall partitions off the shop, fifty feet wide along one side, which will contain the blacksmith forges, tools, heating plant, foremans office, toilets, and lavatories.

The building is of structural steel frame, with tile walls, plastered on the outside, with saw-tooth roof construction. The general construction of the building otherwise is the same as that of the other shop buildings. An overhead trolley beam is provided to permit of handling timbers with a trolley into the shop.

Compressed air, steam and water service piping, and fire protection, including automatic sprinklers, are supplied. Heating is with the indirect fan system, with underground concrete and tile ducts. Lighting is by 100-watt Tungsten lamps.

The location of this building alongside of the lumber yard permits of handling lumber so that it can be passed through into the shop without rehandling.

Planing Mill.—This building is 303 feet long by 80 feet wide, and contains the woodworking machinery. The frame is of structural steel, carried on concrete footings. The general construction of the building is the same as that of the other shop buildings. A track extends through the building longitudinally to permit of movement of material in at one end to the various machines and out through the opposite end with the minimum amount of handling. The



Interior of the Locomotive Shop, Showing 120-Ton Locomotive Crane.

building is located so as to be convenient to the passenger car shop and the freight car shop. The lumber yard is located back of and at one end of the planing mill.

Suitable piping has been provided for distributing compressed air and water. The fire protection system includes automatic sprinklers.

Provision is made for toilets, lavatories, and metal lockers for the men employed in this department.

Heating is by the indirect fan system with galvanized iron heating ducts. Lighting is by mercury vapor lamps.

Boiler House.—This building contains sufficient space for 21,000 horse-power water tube boilers that are required to provide steam for heating the shops and for other purposes for which steam is required throughout the shops. The building is constructed with brick walls carried on concrete foundations, with steel roof trusses and supports for coal bunkers. The chimney is of reinforced concrete, 200 feet high, with a minimum diameter of nine feet.

The overhead coal bunker for each boiler is divided by a reinforced concrete partition into two compartments to provide for storing and burning two kinds of coal. An overhead storage bin for ashes is provided, from which bin the cinders can be discharged by gravity into cars alongside of the building. A concrete dumping hopper is provided outside for dumping coal from cars. A pivot steel elevator raises and discharges the coal into the overhead bunker. A skip-bucket, with electric hoist, handles the ashes into the ash-bin.

The boiler units are 350 horse-power rating, and are set in three batteries of two each. Five of the boilers are equipped with chain grate stokers. The sixth boiler has the shaking grates to burn shavings and other planing mill refuse.

Space is also provided for three electrically driven air-compressors, each of a capacity of 1,500 cubic feet of free air per minute. Only two of these compressors are installed at this time.

Transformers and distributing panel are located in this building for transforming and distributing light and power current to the shop yard, freight car shop, planing mill, and coach repair shop. There is no direct current apparatus in this station.

Provision has been made for two incoming 2,200-volt lines, one of 2,000 k.w. and the second of 1,000 k.w. capacity for breakdown service.

The steam required for the steam hammers and other shop purposes during the summer time can be supplied by one boiler. The boiler capacity provided will afford one spare boiler during the extreme weather conditions when the maximum steam demand occurs.

Yard Crane.—A yard crane runway, 1,260 feet long, extends from the west line of the locomotive shop, and carries a 10-ton high-speed travelling electric crane with 80-foot span, serving the material yard and a portion of the storehouse platform and scrap dock. One of the storehouse tracks extends through under this crane, resulting in giving ample space for the storage of material alongside of the storehouse, foundry and locomotive shop. By this arrangement heavy material can be unloaded, stored, and rehandled to the shop or loaded out again by the crane for shipment, practically eliminating manual labor in the handling of all heavy material.

Miscellaneous Structures.—The transfer table for serving the coach shop is 75 feet long, of 150 tons capacity, equipped with electric motor, with concrete transfer table-pit 400 feet long, extending out far enough at either end of the building for providing entrance and egress at both ends.

The mess building is 269 feet 6 inches long by 31 feet 10 inches wide, of wooden frame construction, covered outside with sheathing, building paper and siding, and sealed on the inside with metal sheathing. It has a concrete floor, and contains a dining-room and lunch room for the workmen and a dining-room for the officials, together with kitchen and pantry. Sixty feet of the length of the building is carried up two stories to provide an apprentice schoolroom and quarters for the help. Heating is by the direct system and lighting with incandescent lamps.

There are also two small buildings located near the freight repair tracks for blacksmith shops and workmen's tools, and in one of them is a small toilet and [illegible]. Dry kiln material bins, plate and iron racks, coal and [illegible] are also provided.

For obtaining water for shop purposes there have been put down two eight-inch wells equipped with electrically operated pumps. To supplement this supply and to provide a main source of supply for fire protection the city of Calgary has brought down into the shop site to a point midway the length of the main shop building on the west side a 10-inch cast-iron water main. The shop service and fire lines are connected onto this main and into a steel tank of 125,000 gallons capacity, which is erected on a 70-foot steel tower, principally for use in connection with automatic sprinklers in the various buildings where these are installed. A complete fire protection system has been put in, with hydrants distributed about the shop yard.

The sewage system in the shop yard may be divided into the sanitary and storm sewers. The city of Calgary is furnishing the main sanitary sewer, beginning at the east line of the freight car shop and extending to the eastern boundary of the shop property. All the sanitary sewage lines from the various buildings are connected into this sewer. Storm sewers are provided where necessary to carry off the roof water from the buildings where the roof construction is such that this cannot be discharged on to the ground.

The location of the shops is about four and one-half miles east of Calgary, practically on the open prairie, and on the beginning of construction arrangements had to be made to house and board on the shop property a considerable quantity of labor. To this end, frame bunk-houses were built with two tiers of bunks on each side of the building, eight bunks long, each house having a capacity of 32 men. Stoves were placed in the centre aisle and benches along the sides of the lower tier of bunks. On the coming of summer and as the labor forces were increased some of the men were housed in standard 12 x 14 wall tents, which accommodated four men each. A large mess-room and kitchen and store-room space was also fitted up with a capacity of feeding about 400 men at one time. Great care was exercised throughout the work in keeping the camp in a sanitary condition. This work was largely under the direction of doctors, who visited the camp each day to take care of all sickness, and an arrangement was also made whereby those who were employed on the work voluntarily contributed a small amount from their wages for the services of these doctors. This amount also included hospital service when necessary. Due to this care there was very little sickness on the job.

As there were no accommodations for men with families near the shops the railroad company put into temporary service a train to carry the men back and forth from Calgary, and several hundred men went back and forth on this train each day. This arrangement helped the situation considerably, especially as the season advanced and all kinds of skilled and unskilled labor became more difficult to obtain. A standing order was placed through several labor agencies in Calgary to send men daily to the job. As the work neared completion the bunk-houses and mess-house previously mentioned were turned over to the railroad to take care of their own men, who were at that time living in cars on the property. This, of course, released the cars and permitted their use at other points.

The progress schedule will show the prosecution of the work, but it should be again pointed out that it was not possible to break ground until April 1st, 1912, and by March 17th, 1913, the locomotive shop was in full operation. When the magnitude of the work is considered, as also its distance from the larger centres, it will be appreciated that a record for prompt performance has been established.

PHŒNIX BRIDGE AND IRON WORKS COMPANY

The Phœnix Bridge and Iron Works Company is making a new issue of bonds and stock this week, through the Quebec Savings and Trust Company. This stock has already been underwritten, and is now being distributed to the public. The offering consists of $750,000 of 6 per cent. first mortgage bonds, and of $800,000 of common stock. The bonds are being offered at 96 per cent. of par, and the stock at $50 per share. The offering is being made simultaneously in London and in Canada. Approximately $450,000 of the bonds and $405,000 of the stock have been taken firm. A new company has just been incorporated at Ottawa with a capitalization of $1,500,000. This company in every way takes the place of the company which has heretofore operated under the same title. After the present issue has been accomplished, there will remain in the treasury to provide funds for future expenses and for the general purposes of the company, $700,000 of the common shares of the company. All the bonds will have been issued.

The Phœnix Bridge and Iron Works Company has a plant situated in the centre of the manufacturing district of Montreal, where shipping facilities are all that could be desired. The concern manufactures and erects structural steel for bridges and buildings. The cost of delivery, owing to the central location of the concern, is smaller than in the case of most other companies. Operations have now been carried on satisfactorily since 1898, and save for an occasional year, earnings have shown a fairly constant increase, beginning with $51,000 in 1898 and progressing gradually to upwards of $600,000 during the past couple of years. The land owned by the company allows of an expansion to the works. The assets of the company, at the end of last year, including $25,000 which is being provided for improvements, amounted to $1,400,000, while total liabilities were but $57,000. This leaves a surplus of $1,243 against the present bond issue of $750,000.

Mr. James W. Pyke is president of the company, and Mr. T. Palmer Howard is general manager.

ABSENCE OF ROADS IS ECONOMIC LOSS

The improvement and maintenance of good roads in the rural districts is a vital problem in all parts of Canada. Inevitably, perhaps, the phenomenal development of railway and waterway navigation has largely overshadowed the necessity that exists for properly built waggon roads. However, it is steadily being more fully realized that the absence of such roads causes an economic loss of great importance to every citizen, and especially those of the rural districts.

Scientific progress is being made in many parts of Canada. The government of Ontario is spending large sums on roads in New Ontario. New Brunswick is enacting "good roads" legislation; and Saskatchewan, where railway development during the past few years has been phenomenal, is carrying out a comprehensive "good roads" policy.

Saskatchewan has appropriated $1,200,000 for highway improvement work during 1913. This is merely a continuation of the work commenced in 1905, and each year since then the government has expended from $200,000 to $700,000 a year on roads and bridges. The work has been carried out under the supervision of a board of highway commissioners, and assistance is granted through them to municipalities under certain carefully defined conditions, states Conservation. This assistance is confined to the building of bridges and trunk roads. The old statute labor system is discouraged as being uneconomical and inefficient.

In view of the scarcity of gravel and stone in many parts of Saskatchewan, extensive experiments have been carried out at provincial expense to ascertain the best means of constructing clay roads. It has been found that Saskatchewan clays burned at comparatively low temperatures produce an excellent surfacing material for graded roads. Owing to the reddish color of this burned clay these roads are known as "the red roads of Saskatchewan." Their cost, where underdrainage is not necessary, has been found to be from $2,000 to $2,500 a mile. This includes the cost of burning the surface clay. Where tile drainage of the grade is essential, the cost is increased by from $1,000 to $1,500 a mile. It is claimed that these roads stand up well under prairie conditions.

Another class of road that is being experimented with in Saskatchewan consists of a specially prepared clay grade covered with asphalt. If suitable to the conditions, such a road should prove popular in the smaller towns and villages.

INSTITUTION OF CIVIL ENGINEERS.

Many of our readers will be interested in learning that Col. H. N. Ruttan, city engineer of Winnipeg, as a result of the ballot for the election of officers for the next session of the Institution of Civil Engineers has been included. The list of gentlemen whose names appear as eligible for election is as follows: President, Mr Anthony George Lyster; vice-presidents, Mr. Benjamin Hall Blyth (Edinburgh), Mr. John Strain (Glasgow), Mr. George Robert Jebb (Birmingham), and Mr. Alexander Ross (London); other members of council, Mr. John A. F. Aspinall (Liverpool), Mr. John A. Brodie (Liverpool), Mr. William B. Bryan (London), Colonel R. E. B. Crompton (London), Mr. J. M. Dobson (London), Sir Hay Frederick Donaldson (London), Mr. E. B. Ellington (London), Mr. W. H. Ellis (Sheffield), Mr. W. Ferguson (Australasia), Sir Maurice Fitzmaurice (London), Sir John Purser Griffith (Dublin), Mr. C. A. Harrison (Newcastle-on-Tyne), Mr. Walter Hunter (London), Mr. Harry E. Jones (London), Sir Thomas Matthews (London), Mr W. H. Maw (London), Mr. C. L. Morgan (London), Mr Basil Mott (London), Mr. A. M. Tippett (South Africa), Sir Philip Watts (London), Mr W. B Worthington (Derby), Mr. Dugald Clerk (London), Mr. Robert S. Highet (India), Mr. Edward Hopkinson (Manchester), Mr. Frederick Palmer (London), and Col. H. N. Ruttan (Winnipeg).

LARGE STEAM PLANT.

Contracts for a steam plant of 60,000 k.w. capacity have been placed recently in New York by Messrs. Guggenheimer & Company, New York, for the Chile Exploration Company. The equipment at present comprises four 10,000 k.w. Siemens generators coupled direct to four 14,300 P. S. Zoelly steam turbines of Escher Wyss & Company manufacture, Zurich. These units will run at 1,500 r.p.m. when working with steam of 170 pounds pressure and 325° Centigrades superheat. Escher, Wyss & Company, Montreal, who are attending to the American business of their works, Zurich, have secured this order against competition from the foremost American and European makers on the strength of the low steam consumption of their turbine.

The plant is to be installed in Chile, and the power used for electric smelting of copper ore. The transmission line, which is of 200 miles length, will be for 110,000 volts pressure. Messrs. Siemens, Schuckert Werke have been awarded the contract for the whole of the electrical equipment.

CONTENTS OF THIS ISSUE.

OIL ENGINES FOR MARINE SERVICE.

While Canada may not, perhaps, stand out conspicuously as a country that has shown very great development along shipbuilding and marine engineering lines, there has doubtless during the past few years been a great impetus given to the shipbuilding and marine engine industry in this country, and there is every reason to believe that this will continue to go on indefinitely. For that reason it is interesting to note the changes that have recently taken place, so far as the adaptation of the oil engine to marine purposes is concerned.

A report just issued by the committee of Lloyds' Register calls attention to the fact that the British Admiralty during the past year have placed contracts for marine oil engines greater in power than ever anything attempted. This report states that there are Diesel oil engines now being built for thirty-four marine vessels, these vessels ranging in tonnage from two to two thousand tons, and the engines of various types ranging in power from 750 to 120 brake horse-power per set. This report states that from January 1st, 1910, to the present time there have been completed in the United Kingdom under the survey of the society fifteen oil-carrying vessels and nineteen other vessels constructed with oil-fuel bunkers. This will give our readers some idea of the work that is going on looking toward replacement of coal by oil for marine purposes. It furthermore states that five large engineering firms on the Clyde are now in a position to make Diesel oil engines for the largest class of ocean-going ships. All along the line the demand for steamers with oil fuel furnaces is increasing very greatly. Not only in Great Britain, but in other countries, this subject has been given a great deal of attention. Russia stands out notably as a country in which this work has been attempted in the most vigorous manner, and altogether it looks as though the oil engine, so far as its application to marine purposes is concerned, is quickly coming into its own.

This development is not without significance and interest for those connected with the shipbuilding industry in Canada, as signs are not altogether wanting which point to bigger things being accomplished by the yards in Canada in the days that are to come.

THE COMMERCIAL TREND OF THE PRODUCER GAS POWER PLANT.

In investigating general problems that relate to the fuel resources of the country and in testing fuels belonging to or for the use of the Government, the Bureau of Mines of the United States has given considerable attention to the efficiency and economic value of producer-gas power plants. Its engineers during the past eight years not only have shown a very low fuel consumption per horse-power hour for these plants, but have demonstrated conclusively the possibility of utilizing commercially low grades of bituminous coal, lignite, and peat in plants properly designed for the use of those fuels. The anthracite plant has been recognized as a commercial possibility for several years, although the cost of the fuel used has in general restricted these plants to comparatively small units.

The commercial development of the producer-gas power plant in America has been largely within the past six or eight years. The feeling of doubt in the minds of many regarding the future of the industry has led the Bureau of Mines to publish in a brochure the results of

their investigations. This feeling of doubt was fostered by the extensive introduction of the steam turbine and the increased interest in the oil engine. During the past three years the belief of many who were formerly firm believers in the gas producer has been that this type of power has reached its height of development, and that from a commercial standpoint it can no longer be regarded as a complete success.

The results of these investigations and the facts gleaned from an inspection of the summaries and charts presented are far from revealing the condition thought to be the case by those who have regarded the immediate downfall of the producer as inevitable.

It is probable that at the present time there are in the United States 900 or 1,000 producer gas-power plants, ranging in size from 15 horse-power to several thousand horse-power.

During the past three years the number of anthracite plants over 500 horse-power rating has increased 263 per cent., and the total horse-power represented by these plants has increased in the same period 242 per cent.

During the same period the number of bituminous-coal plants of 500 horse-power rating or less has increased 118 per cent., and the total horse-power represented by these small bituminous-coal plants has increased 89 per cent.

At the present time producer-gas plants representing nearly 85 per cent. of the total number of installations in this country are operating on anthracite.

Of the total horse-power listed, approximately 48 per cent. is derived from anthracite and nearly 52 per cent. from bituminous coal and lignite.

In 1909 the bituminous-coal plants averaged 12.5 times the size of the anthracite plants, but the introduction of the larger anthracite plants and of the smaller bituminous-coal plants makes the ratio for 1912 about 7.5 to 1.

The use of the small bituminous-coal producer is increasing, and an examination of the complete list of installations reveals several suction plants operating on bituminous coal. Their development is one of the most important steps in the producer field.

OTTAWA CONVENTION OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

Mr. Charles Warren Hunt, secretary of the American Society of Civil Engineers, sends us the following information in connection with the forty-fifth annual convention, which is to be held in Ottawa June 17th to 20th. In a recent issue we gave some information concerning this convention, and we are glad to be able to add to this, and trust that many of our readers will have the opportunity of visiting Ottawa during convention week:—

The headquarters of the society, secretary's office, etc., will be in the Chateau Laurier. All members attending the convention are requested to register in the secretary's office in this hotel as soon as possible after arrival in order that lists of those in attendance may be printed promptly for distribution.

The Eastern Canadian Passenger Association, the New England Passenger Association (with the exception of the Bangor and Aroostook Railroad and the Eastern Steamship Corporation) and the Trunk Line Association (with the exception of the New York, Ontario and Western) have authorized a reduced rate of one fare and three-fifths, on the certificate plan, for the round trip between any point in their territories and Ottawa. This concession is conditional upon the presentation of at least 100 certificates.

To obtain this rate a first-class through ticket to Ottawa, Canada (either limited or unlimited), must be purchased, and a certificate obtained from the ticket agent that such purchase has been made. If a through ticket cannot be purchased, then a local ticket should be obtained to the nearest point where a through ticket can be obtained for the remaining distance to the place of meeting.

Tickets for the return trip over that part of the route covered by such certificates will be sold, at three-fifths the highest limited fare, to those persons, and those only, who hold the certificates signed by the ticket agent at the point where through tickets to the place of meeting were purchased, and countersigned also by the secretary of the society, certifying that the holders have been in attendance at the convention.

Tickets on this plan cannot be purchased more than three days (exclusive of Sunday) before the time of meeting, and return tickets must be purchased within three days (exclusive of Sunday) after the date of adjournment.

Particular attention is called to the request made by the Passenger Associations that persons desiring to avail themselves of the reduced rates be at the offices for certificates and tickets at least thirty minutes before the departure of trains. Also that these rates are applicable only to through tickets to Ottawa, Canada.

Programme.

Tuesday, June 17th.—At 3 p.m. there will be a reception by the Premier, the Right Honorable R. L. Borden, and the mayor of Ottawa, at the Chateau Laurier.

Evening.—At 9 p.m. the president and officers of the society will hold an informal reception at the Chateau Laurier. Dancing may be expected.

Wednesday, June 18th.—At 10 a.m. the first session will be called to order, and the president will deliver the annual address, after which the business meeting will convene. The time and place for holding the annual convention of 1914, and several proposed amendments to the constitution will be considered, and other business transacted.

Afternoon.—Members and guests are invited to a garden party at the residence of T. C. Keefer, C.M.G., past-president, Am. Soc. C.E.

Evening.—There will be an illustrated lecture on Canadian engineering subjects in the ballroom of the Chateau Laurier. It is expected that the subjects covered will be: Transportation Routes in Canada, the Transcontinental Railway, Canadian Water Powers, Navigation, and Grain Elevators on the Great Lakes.

Thursday, June 19th.—The local committee will announce the programme for this morning at the business meeting.

Afternoon.—There will be a motor drive through the city, visiting the Parliament Buildings, Rockcliffe Park, Rideau Hall grounds, the Experimental Farm, the Chaudière, etc., and ending at 4.50 p.m. at the residence of one of the oldest members of the society, Sir Sandford Fleming, for afternoon tea.

Evening.—The Canadian Society of Civil Engineers will tender a reception to the members and guests of the American Society of Civil Engineers at the Chateau Laurier, with dancing.

Friday, June 20th.—The arrangements for Friday will be announced at the business meeting.

For those interested it should also be stated that the Royal Golf Club, which is within easy reach of the hotels by trolley, will be open to the use of our members during the convention.

S. P. Brown, M. Am. Soc. C.E., has invited all members who pass through Montreal to visit and inspect the new Mount Royal Tunnel of the Canadian Northern Railroad in that city.

TERMINAL PASSENGER STATIONS: THEIR DESIGN AND OPERATION.

By J. L. Busfield, B.Sc., A.C.G.I.

The definition of a terminal as given by the American Railway Engineering and Maintenance of Way Association, now the American Railway Engineering Association, is "an assemblage of facilities provided by a railway at a terminal or at intermediate points on its line for the purpose of assembling, breaking up and relaying trains," and also the definition of a passenger terminal is given as "the arrangement of terminal facilities for the handling of passenger business." These definitions clearly bringing out the fact that a passenger terminal is not only a station where all trains complete their run by stopping at a number of dead-end tracks, but refers equally well to a station where there are a number of through tracks, and where possibly some of the trains pass right through the terminal without any other delay than what is necessary for taking on and setting off passengers and baggage. From this it will be seen that passenger terminals in general can be divided into two classes, viz., terminals of the dead-end type, and those of the through track type.

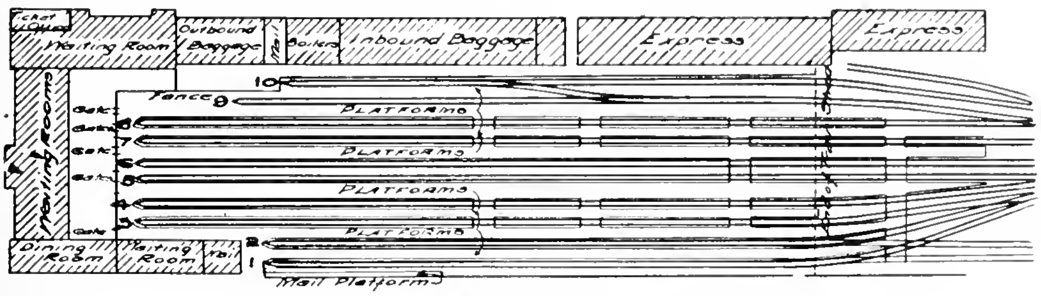

Fig. 1.—Dearborn Station, Chicago.

In a large city or town it rarely happens that a railway company is given very much choice in the selection of a site for a station, because it is tied down by the location of the railway and other controlling features. But wherever it is possible a terminal should be located as close to the hotel and residential district as possible, unless a very large suburban business is anticipated, when it is advisable to have the terminal closer to the business district. These features are well illustrated in the city of Montreal. The Grand Trunk Railway has its Bonaventure station situated about two minutes closer to the business district than the Canadian Pacific Windsor Street station, with the result that it gets about 75 per cent. or more of the suburban traffic to the Lake Shore where there is competition between the two railways, and on the other hand the C.P.R. station is more conveniently situated with regard to hotels, the residential and shopping districts, and again the Canadian Northern has selected a site right in the heart of the hotel and shopping district, and which is also within easy reach of the business section of the city.

Other factors which have also to be taken into account in the selection of a suitable location are the land available, its general size and shape; it should also be convenient and easy of access, and the question of the relative cost of buying the land and the cost of building have to be given consideration.

There are practically no railways with such unlimited resources that expense is no consideration, so, in selecting site, designs, etc., for a passenger terminal, the different possible projects have to be balanced against each other, and usually some desirable features have to be discarded, and the railway company, taking into consideration its resources available, determines which features are most essential to the welfare of the public and the improvement of the service as a whole.

The primary object of a railway's existence is transportation, consequently the railway's first attention must be given to the necessities of transportation, viz., the railway tracks, cars and motive power. In addition to these, of course, there are many accessories which are almost as important, and among these accessories are the numerous station buildings from the small one-man wayside station to the big city terminal which go to make up a big railway system.

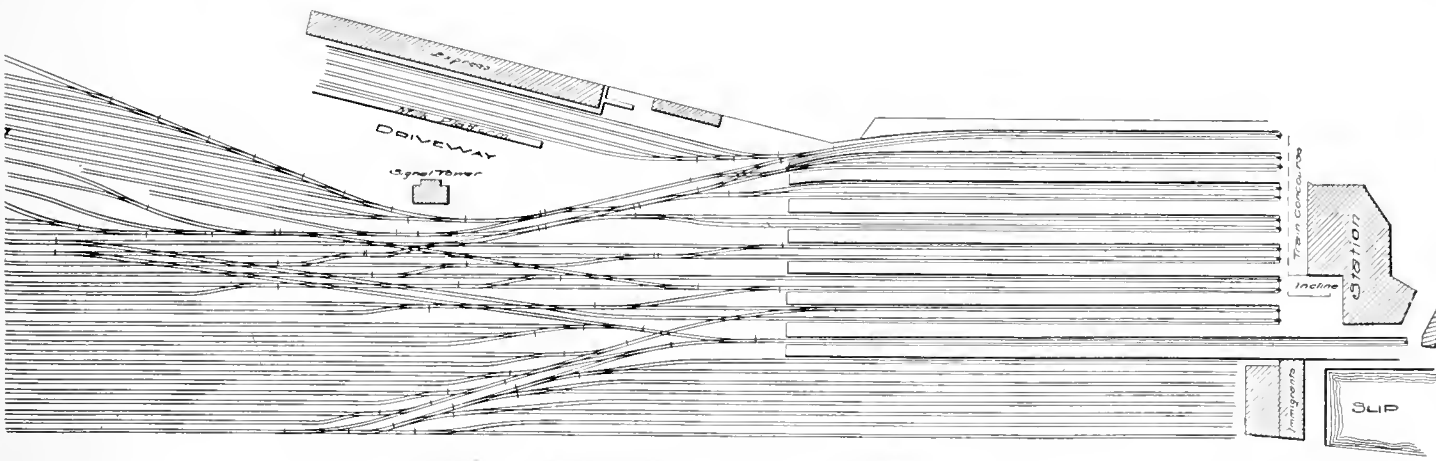

Fig. 2.—Delaware, Lackawanna and Western Railroad, Hoboken, N.J.

When the architects take over the design of a station building, they have to give consideration to the general character of the neighborhood and community in which the station is to be built. The general public usually require and demand that the station building should not only be up to the general standard of public and private buildings in the community, but that they should also set a higher mark for future developments of the community. To what extent the railway company will be controlled by the wishes of the

community will depend largely on the resources of the railway and also on local conditions of competition, but it will be usually found that the interests of the railway and the public desires are very closely allied.

Limitations are imposed upon the architect, such as the size and shape of the land available, but everything should be subordinated by him to the convenience and comfort of the travelling public, and to the economic and efficient handling of the railway company's business.

Care should be taken that architectural effect should be subordinate to utility. The building should, of course, be made handsome and agreeable without undue expense, but sometimes stations have been designed with very beautiful and artistic effect, and with little regard for the convenience of the people who use it, and on the other hand some very plain and ugly buildings are the very best from the viewpoint of comfort and expeditious handling of passengers and the accompanying facilities. The ideal is obtained when a station is designed to give the maximum comfort to the public, and which also has a pleasing exterior and interior appearance.

The necessary size of a terminal is a very difficult question for the railway and architects to deal with. The controlling feature is not only the number of passengers likely

Central station, New York, where the suburban tracks are kept below the main line. The fact that passengers will take the line of least resistance must also be kept well in mind. In a station with a large amount of through traffic there are always a great number of strangers who should be provided for in the way of indicators and sign-boards denoting waiting rooms, ticket, parcel and inquiry office, baggage rooms, etc. Lighting is also a very important feature, and the architect or engineer who designs a terminal with a maximum of daylight and with the best lighting at night without undue expense is to be praised.

Another detail which is sometimes lost sight of is cleanliness. With steam traction, locomotive dust and smoke are unavoidable, and in the interior, the building will be used by all sorts and conditions of men, women and children, so both in the selection of building materials and in also the interior decoration, this should be considered and the station designed with a minimum of carvings, mouldings, ledges, etc., and some form of interior decoration used which can readily be cleansed. This feature of cleanliness is one that should be absolutely insisted upon.

The exterior of a station building should, of course, be designed to be distinctive, and not to look like a hotel or factory, and this can best be obtained by a symmetry of lines

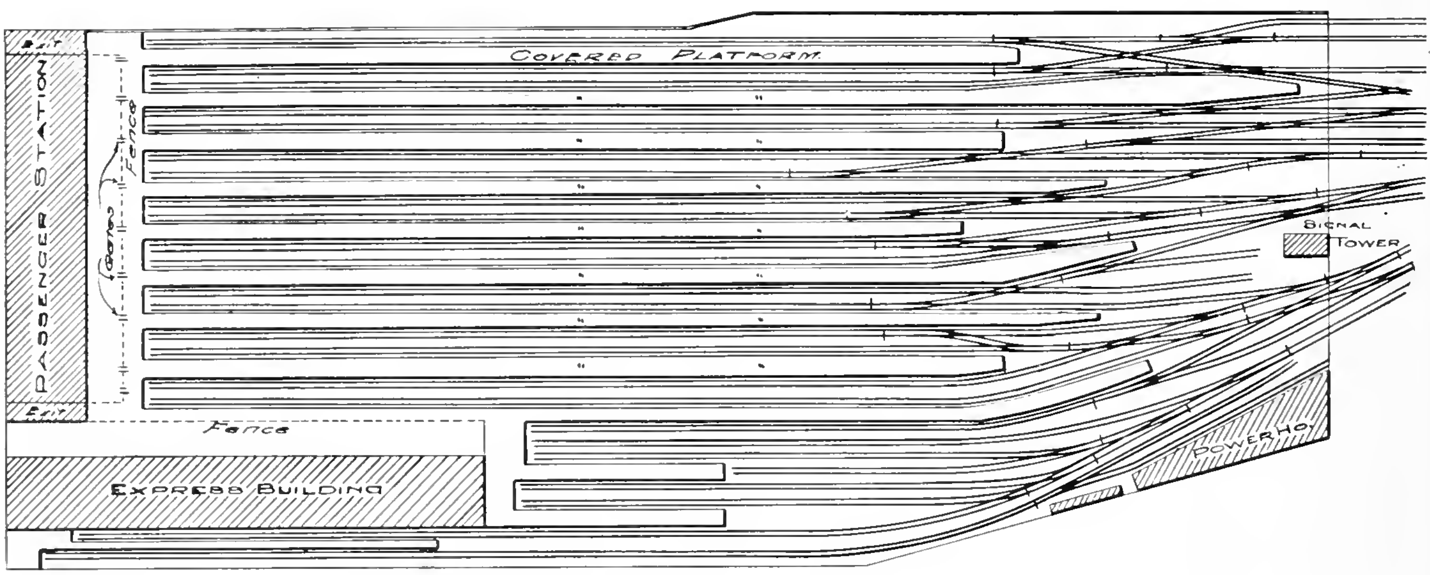

Fig. 3.—Long Island Railway Terminal, Long Island City.

to be using the station but also the rate at which they are going to use it, and the general nature of travel from the station. Again, the railway company has to take into consideration the growth of its business and design its terminal to take care of the business expected in 10 or 20 years' time.

The character of the traffic through the station makes a big difference in its general design. The station which is to provide for a large percentage of through main line travel must be provided with large waiting rooms, lunch counters, baggage facilities, etc., whereas a station with a large preponderance of suburban traffic should be designed to give easy and rapid access for large numbers of people between the platforms and streets. The suburban passenger has no occasion to stay any length of time and frequently only allows himself the minimum of time to catch his train. In a large terminal where there is a large quantity of both through and suburban traffic it is sometimes desirable to separate the two kinds entirely, avoiding considerable confusion and congestion. This is effectively done at the Grand

and masses rather than by decorative features. A good idea is to have a clock in a prominent position, on account of the close connection in the traveller's mind of time and trains.

In a great many cases the design and general size and shape of the terminal station building is dependent on the layout of the tracks and platforms at the station. These in turn are dependent on the method of operating the yard, so that in order to design the track layout the engineer must be thoroughly conversant with this method. This, again, is dependent on the nature of the traffic, number of trains handled and the rapidity with which they have to be handled, and also on the proportions of through and terminal traffic, and sundry other features which will be discussed in connection with some of the terminals of which a short description will be given.

With regard to the track layouts, terminal stations can be divided into three classes, namely, dead-end stations, through track stations and, thirdly, stations with both through and stub tracks.

In terminals of the dead-end class, the station building is usually located at the end of the tracks which is known as the headhouse type, or else it is located partly at the end and partly to one side of the tracks. The Dearborn (Polk Street) station at Chicago is a typical example of a terminal of the headhouse type. A plan of this station is shown in Fig. 1, and, as will be seen, there are two tracks which accommodate the business of the owners. The Chicago & Western Indiana Railroad and also its tenants, the Grand Trunk, Erie, Chicago-Indianapolis, Louisville, Wabash and Santa Fe Railways. The station is operated by the Chicago & Western Indiana Railroad.

Tracks 1 and 2 in Fig. 1 are mostly used for mail, but occasionally at rush times they are used for passenger trains. Tracks 3 to 8 are used generally for suburban and main line trains. Nos. 9 and 10 are used for express and baggage. The platforms average about 670 feet in length, and are 6 inches above the tops of the rails. After the passengers have disembarked from a train, the Pullmans and day coaches are hauled by a switching engine to the car storage and cleaning yards, about 5½ miles away, where they are cleaned and turned preparatory to their return journey. The baggage and express coaches are placed on tracks 9 and 10, and the mail coaches on track No. 1. On account of the number of companies using the station and the comparatively small number of tracks, no particular platforms are assigned for the arrival of trains, but they are simply put into whichever one may be empty at the time.

Another terminal of the same type, but considerably larger, is that of the Delaware, Lackawanna & Western Railway at Hoboken, N.J., illustrated in Fig. 2. At this terminal there are 127 originating and 118 terminating trains daily. These trains are handled on 14 tracks placed at 13 feet centres. There are eight platforms 20 feet wide and one 17 feet wide, 700 feet long and placed 9½ inches above the tops of the rails. After the incoming trains have been unloaded the main line locomotive, or sometimes a switch engine, takes the trains to the storage and cleaning yards. The outbound trains are made up in the coach yard and pushed towards the train shed, into which they are dropped by gravity. Each train is operated from a certain track in accordance with a regular schedule in the possession of all the station employees. Local express is handled from the express building by trucks to the various trains. The through express is all loaded into cars placed alongside the express building.

The Long Island Railroad has a terminal of the headhouse type at Long Island City. There are 135 outbound and 134 inbound trains handled at this terminal every day. There are 17 tracks in the train shed and seven others for baggage and express, as shown in Fig. 3. There are nine passenger platforms 14 feet wide and 760 feet long, placed 9 inches above the rails.

When an inbound train has been unloaded it is backed out by the main line locomotive to the car storage yard about ¼ mile away. It is here cleaned and switched and made up ready for its return journey. The express and baggage are handled on the south side of the station when in carload lots. The baggage cars are switched from the car storage yard as soon as the train is backed out of the train shed, and are taken by a switching engine to an express platform.

A station of the headhouse stub track type is that of the London, Brighton & South Coast Railway at Victoria, London, England. This station has a very novel arrangement of tracks which was designed by Mr. C. L. Morgan, chief engineer, to suit the peculiar local conditions. Some years ago the capacity of the station became too small to handle the amount of business the company was obtaining, so the question of remodelling and enlarging the station was brought up. In looking into this problem the railway company found themselves hemmed into a comparatively narrow site between Buckingham Palace Road on one side and the South Eastern and Chatham Railway on the other. A certain amount of widening was possible, but not enough for satisfactory results, consequently the station shown in Fig 4 was designed to meet the requirements. The novel feature of this arrangement is that the platforms are made long enough to accommodate two standard trains, and the tracks are so arranged that trains can arrive at or leave the inner end of the platforms without interfering with trains at the outer end. This is effected by placing groups of three tracks between the platforms at the outer ends, which are reduced with convenient switches and crossovers to two tracks at the inner ends. The old station originally accommodated six trains, whereas the new layout provides platform and track space for 18 trains.

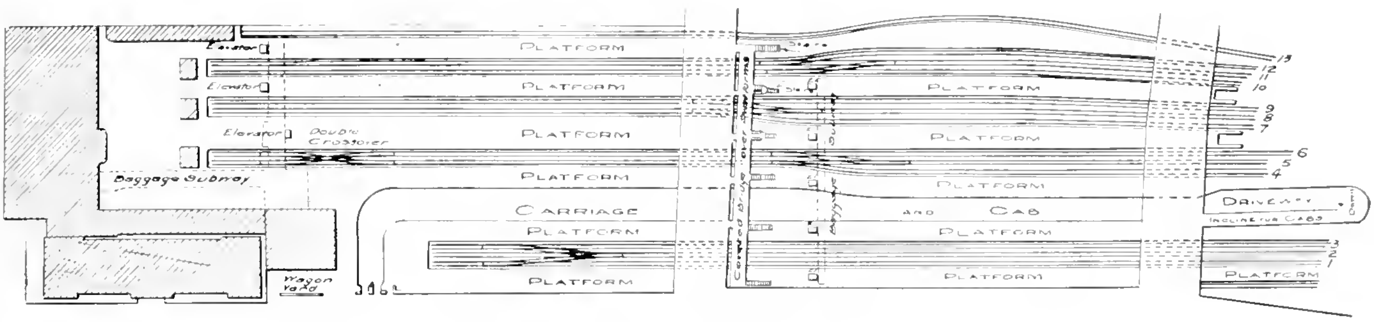

Fig. 4.—London, Brighton and South Coast Railway, Victoria Station.

The method of handling suburban trains during the rush hours is of interest. Supposing track No. 6 in the accompanying plan to be clear and an incoming train is allowed to enter right up to the inner portion. A following train can then run in behind it and stop at the outer portion of the platform. While this train is pulling in and unloading its passengers the engine of the first train can run around it and couple on the rear end, which now becomes the front end, and it is all ready to commence its trip via track No. 5 without interfering with the second train at all. An alternative arrangement is for an engine to wait on the middle track until the first train has pulled in, and then take the crossover and connect on to its rear end. After the first train has pulled out the second one can pull in to the end of the platform to take outgoing passengers, and its engine can run around it as before, or else the engine of the foregoing train will couple on to its rear end.

(To be continued.)

AN INTERESTING FILTER INSTALLATION.

Probably no one phase of municipal engineering has attracted so much attention during the past few years, at least in Canada, than that which has to do with the securing and maintenance of a proper and adequate water supply.

In Canada, where new municipalities are coming into being so quickly, and existing communities are growing so rapidly, it is quite natural to find such a great interest in this subject.

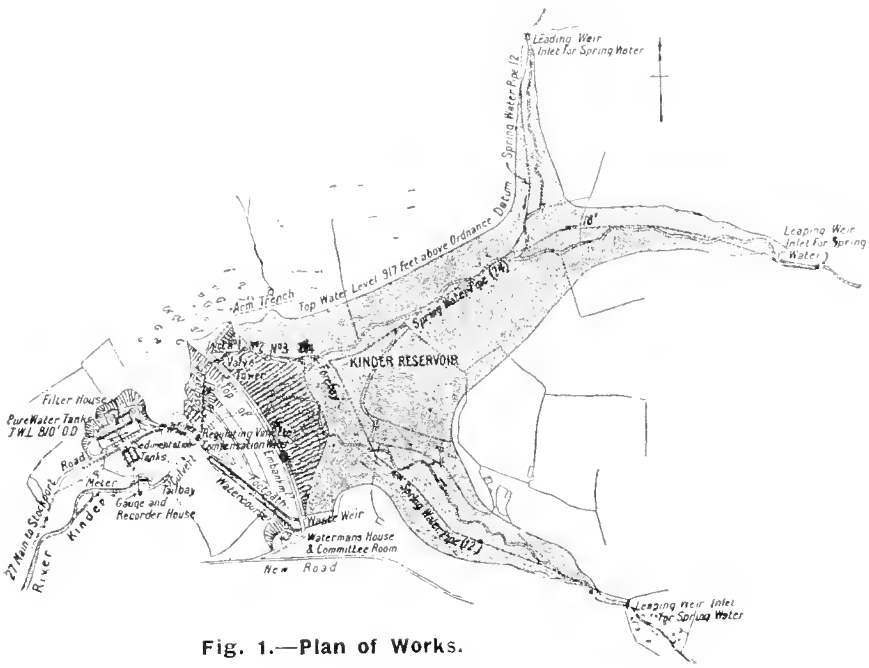

Fig. 1.—Plan of Works.

In order to place before the municipal engineers of Canada information concerning various types of filters used in Canada itself, the United States and Great Britain, *The Canadian Engineer* has, during the past few years, published descriptions of various filter installations. By studying the characteristic features of these various plants municipal engineers have been enabled to form some idea as to their relative values and thus be able to judge intelligently when brought face to face with the question themselves.

This particular article deals with an English installation, that at Stockport, which plant has a number of features which we feel sure our readers would like to be informed about.

The filtration plant proper is located at Kinder, near Stockport, named after the river upon which the reservoir is built. The engineers for the work were Messrs. G. H. Hill and Company, of Manchester. The reservoir in connection with this plant has a capacity of 515 million gallons, an area of 44 acres situated in the valley of the River Kinder. A plan of the layout will be found in Fig. 1.

The filter house, shown in Fig. 2, is built of common brick faced with stone work and is 180 feet long by 39 feet 6 inches wide, with an annex 30 feet 6 inches long by 35 feet 6 inches wide. Light for the filter house is secured by means of sky-lights in the roof. The installation called for twenty-four No. 5 Bell patent filters (provision having been made for an additional eight) and these batteries are so arranged that they can be operated as a whole or entirely separate. Fig. 3 shows a general view of the interior of the filter house and will give the reader a clear idea as to the arrangement as well as the interior construction of the house, methods of lighting, etc.

The filters consist of steel shells having hydraulically dished and flanged ends in which are placed pebble strainers which will allow the filtered water to pass through every passage, absolutely preventing the escape of filtering material. The filtering medium rests on the top of the strainer. Fixed in each shell and passing through the centre of the bed, is a hydraulic central shaft to which is connected a number of horizontal wash arms which in turn are provided with special valves and rakes. This hydraulic shaft is only used when the filter beds are to be cleaned. The two rows of four filters forming the batteries have specially constructed turbines, fitted on the end of the inlet pipe which revolve according to the flow of water passing through the filters, working in turn pumps which take their supply of standard alumina solution from small tanks and force the same into the water supply on its way for filtration. After the alumina has been applied the water is agitated and thoroughly mixed while passing through the turbines. Each of these batteries is supplied with a Venturi meter, which accurately registers the amount of water filtered and the amount of wash water.

It will be seen from Fig. 3 that the overhead travelling crane of suitable capacity is provided for, and in order to facilitate manipulation, the marine type of platform is arranged along the top of the filters.

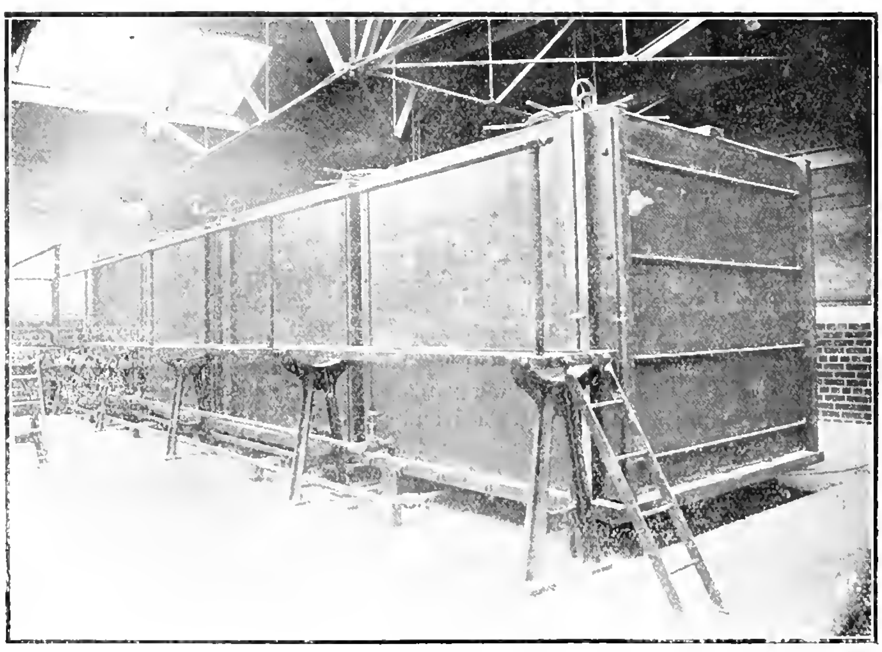

Fig. 4.—Alumina Tanks.

Each of these filters has a diameter of 8 feet and has a capacity of 3,000,750 gallons per day of twenty four hours.

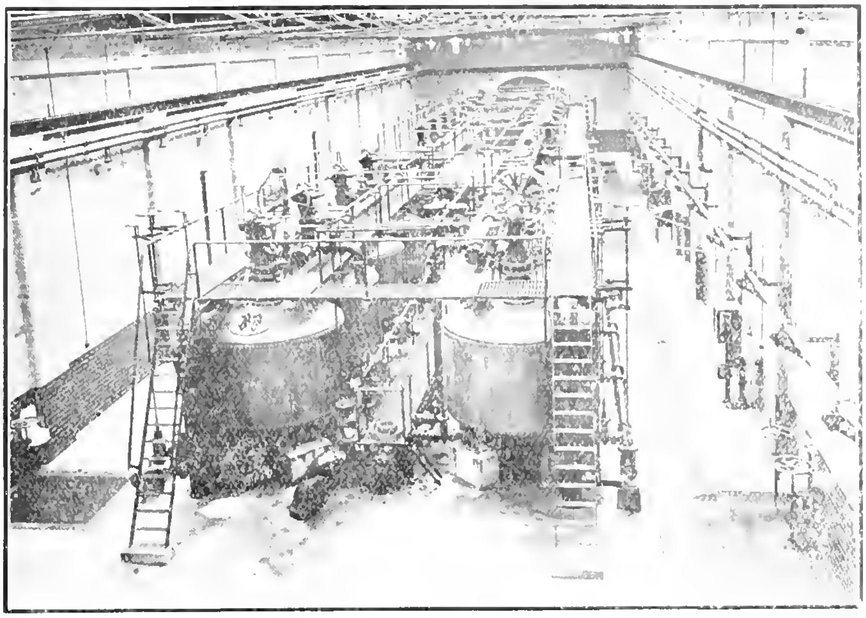

Fig. 3.—General View of Filter House Interior.

After passing through the filter, the water goes into two covered tanks in the adjoining house and with a capacity of 250,000 gallons each, which are purposely reserved for that purpose. These tanks serve to equalize the delivery of filter water to the trunk main and thus avoid direct draughts being made upon the filters themselves.

In the annex referred to are placed the lime and alumina tanks, as well as the machinery for actuating the washing mechanism of the filters and the electric lighting plant. The alumina solution tanks are shown in Fig. 4, and the gauge will be noticed at the nearest end of the tank just next to the ladder. These tanks have their own flow indicator and gauge and are so arranged that they maintain a constant supply to a distributing tank with a ball valve in the filter house.

Cleansing of the filters is done once every 24 hours and takes for the 24 filters about thirty minutes. This cleansing is accomplished by reversing the current of clean water through the filters, at the same time passing a current of

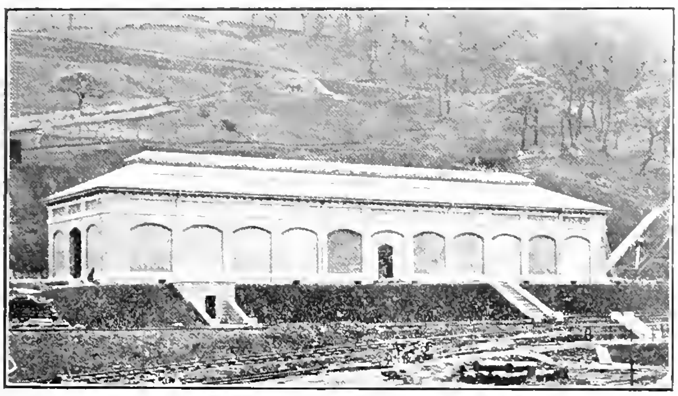

Fig. 2.—Showing Filter House.

clean water into the hollow shafts and wash arms, and also revolving the wash arms through the bed by means of a gearing supplied for that purpose. In this way the whole of the impurities which have accumulated in the filters are quickly separated from the filtering material and carried out through the washout valves and bell mouth to the sedimentation tanks. The quantity of wash water used is about three-quarters of one per cent. of the total amount filtered. After this is done the impurities in the wash water quickly precipitate in these tanks and the clear water is then discharged into the river. When cleansing is done it is only the filtered water from the other filters that is used for the purpose.

The process of washing out and stirring is continued until the water issuing from the washout tap is quite clear and free from dirt.

As showing the efficiency of the Stockport plant attached, we print herewith a report and test made by Sheridan Delepine, M.B., C.M.M.Sc., assistant director of the Public Health Laboratory, University of Manchester, under date of December 21, 1912. This report speaks for itself.

The Bell Filtration Company of Canada, Toronto, the Canadian company building the filters of the type herein described, have just completed the installation of a plant at Haileybury, Ont.

MODERN BLUE-PRINTING.

By P. M. Morgan.*

The Pease "Peerless" continuous blue-printing equipment prints, washes and dries the paper automatically, delivering the prints at the end of the dryer in a loose roll, free from wrinkles or distortions, and ready for immediate use.

So noiseless is this apparatus in operation, owing to the method used for electrically controlling the speeds, that there is no objection to placing it in the drafting room. The entire apparatus occupies a floor space of only 5½ x 6½ feet.

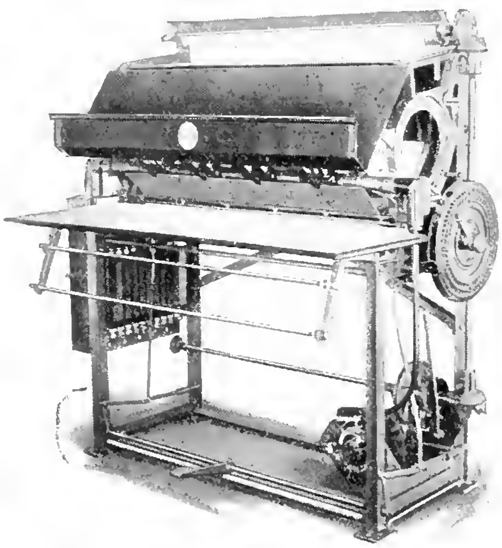

Fig. 1.

and there is no dirt or other objectionable features. It is easily possible for one operator to print, wash and dry 100 yards of blue-print paper per hour, the apparatus consuming during that time only 7 kw. of electric energy, 60 gallons of water, and 50 cubic feet of gas. Where a smaller outfit is desired it is equally practical to operate the machine for ten or fifteen minutes at a time and effect a considerable saving in the time and labor usually required in washing and drying. The printing machine can be used independently at any time if desired for an occasional print.

It can readily be seen that by placing this apparatus in the corner of the drafting room, the operator's time, when he is not engaged in operating the machine, can be used to excellent advantage for other work about the drafting room. These machines were designed for general practicability for all classes of electric printing, and with especial reference to low operating and maintenance expense. They are built in various sizes, to suit the largest or smallest engineering department.

Fig. 1 shows the machine ready for operation. The paper may be printed in sheets or in rolls as desired. Two spindles are provided underneath the feeding table for carrying different widths of paper. The tracings and paper are carried upward past a bank of arc lamps by means of an endless canvas belt. The tracings are returned direct to the operator's hand as he stands in front of the machine; which is a most important feature, as much saving of time is effected in this way. The exposed paper may be returned in the same way or pass over the top roll of the machine. The exposed paper may immediately be seen and the correct exposure obtained before any prints are spoiled, merely by moving the finger on the dial of the rheostat which is placed on the end of the machine convenient to the operator's right hand.

No transparent bands or expensive glass cylinders are used, but in place thereof a short segment of heavy plate glass, which is so mounted and adjusted that breakage is practically impossible. Tension springs at either end of the machine automatically take up the stretch of the canvas belt, so that the most perfect contact between tracing and paper is obtained at all times, while a special device prevents side travel of the belt. Fig. 2 shows the machine with the heavy enameled iron tracing tray pushed back and one lamp turned down on the table, illustrating the method employed for trimming the carbons and cleaning the globes. These arc lamps were especially designed for this machine. It will be noted that they are connected in at the bottom, and each lamp is provided with an aluminum reflector. The resistance coils are carried away from the lamps underneath the table, thereby producing a uniform light and largely reducing the heat. All wiring is encased in steel tubing, and each lamp and motor is independently connected, the switches being enclosed in a metal box at the left-hand end of the machine. By means of the individual connection it is necessary to use only a sufficient number of lamps to cover the width of the tracing being printed. No friction discs or belts are used for controlling speeds, all speeds being electrically controlled directly through the motor. Any possible speed can be obtained, from four inches per minute, which allows sufficient exposure for the slowest negatives or black line prints, up to six feet per minute, which our experience has demonstrated is as fast as the average run of tracings can be properly fed to secure the greatest efficiency from electric energy consumed. A fan is provided for circulating the air, as shown on the left-hand end of the machine.

Fig. 3 shows the blue-printer connected with the Pease automatic washing and drying machine. The paper passes over the top roll of the printing machine into the washer,

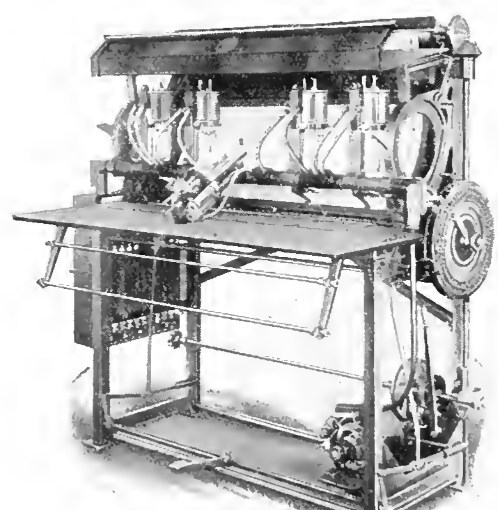

Fig. 2.

where it is first washed by a spray of clear water; then by a weak solution of bichromate of potash which is pumped over and over from the tank shown in the rear of the machine; and lastly by a spray of clear water, after which the paper passes up over the dryer and down into the winding-up device. The printing machine may be used independently

* Vice-president, The C. F. Pease Co., Chicago, Ill.

when desired by simply pulling out a clutch on the washing and drying machine.

When the apparatus is not in use it is customary to keep it threaded up with a strip of blank paper, one end extending onto the end of the feeding table of the printer, and the other end into the re-winding device. After the run is finished the leader is placed on one of the spindles under the feeding table, the sensitized paper is cut off a few inches beyond the

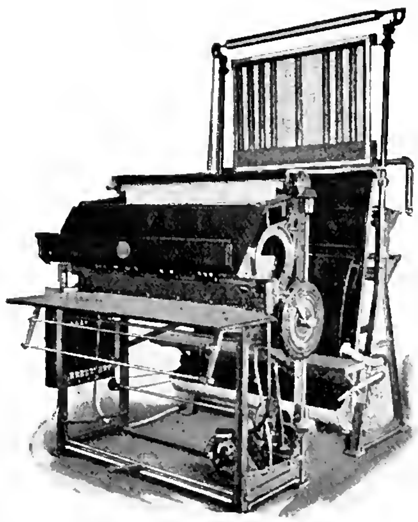

Fig. 3.

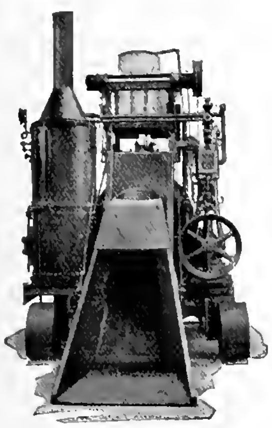
end of the last tracing, and the end is pasted onto the end of the leader, the machine being allowed to run until all of the prints have passed into the winding-up device and the leader is again in the machine ready for starting.

NEW STREET PAVER.

The Chain Belt Company, Milwaukee, Wis., announce that they are now manufacturing a paver. The machine is provided with a reversible traction drive so that it can be moved forward or backward by its own power. The traction drive is fitted with a friction clutch. It is connected to both rear wheels and is sufficiently powerful to propel the machine up an incline of 15 degrees.



Charging Side of Street Paver.

No platforms or runways are required and if the material is placed sufficiently close to the machine it can be shovelled directly from the supply pile to the open end power loader bucket. The paver is equipped with a boom 20 feet long and delivery bucket. The concrete is discharged from the mixer into the delivery bucket, which travels on a single boom. The boom can be swung at an angle of 180 degrees, and a street 50 feet wide can be taken care of. The boom bucket will hold a full batch of the mixed concrete and is provided with an automatic tripper. The gates open up automatically at any place where it is desired to deposit the concrete. When the bucket returns to the mixer, the gate closes automatically. In work where the road is less than 18 feet in width a gravity swivel chute may be substituted for the distributing boom.

ILLUMINATING ENGINEERING SOCIETY.

At a meeting of the Convention Committee of the Illuminating Engineering Society, held in Pittsburgh, Friday, May 16th, it was decided to hold the next annual convention in that city during the week beginning September 22nd.

The Convention Committee consists of Mr. C. A. Littlefield, New York Edison Company, chairman; Mr. P. S. Miller, Electrical Testing Laboratories, president of the Society; Mr. H. S. Evans, Macbeth Evans Glass Company, Pittsburgh, Pa.; Mr. W. A. Donkin, contract manager Duquesne Light Company, Pittsburgh, Pa.; Mr. D. McFarlan Moore, General Electric Company, Harrison, N.J.; Mr. M. C. Rypinski, Westinghouse Electric and Manufacturing Company, New York; Mr. C. J. Mundo, General Electric Company, Pittsburgh, Pa.; Mr. J. C. McQuiston, Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa.; Mr. W. J. Sterrill, United Gas Improvement Company, Philadelphia, Pa.; Mr. S. B. Stewart, Philadelphia Company, Pittsburgh, Pa.; Mr. T. J. Pace, Westinghouse Electric and Manufacturing Company, Pittsburgh, and Prof. H. S. Hower, Carnegie Technical Schools, chairman of the Local Section of the Society.

Mr. W. A. Donkin, of the Duquesne Light Company, was selected as chairman of the Local Committee on Arrangements, which will have charge of the Convention. Mr. J. C. McQuiston, of the Westinghouse Electric and Manufacturing Company, was appointed chairman of the Publicity Committee, and will make all arrangements for advertising the Convention.

It is expected that several hundred engineers from all parts of the country interested in lighting in its various forms will be present, and the progrmme, details of which have not as yet been completed, will consist, in addition to the technical sessions, of a reception and dance, several excursion trips and visits to various industries in Pittsburgh.

CHICAGO RAILROADS ON ELECTRIFICATION.

Eight of the steam roads which enter Chicago made a joint statement to the committee on railway terminals of the city council, on May 12th, and requested that action be deferred until another year on a proposed ordinance, which, while it does not specifically require electrification, under the police authority of the city orders an abatement of all the nuisances occasioned by the operation of locomotives. The statement points out that the railroad situation in Chicago "is entirely different from that in any other part of the United States where electrification of terminals has been attempted."

In order to keep pace with the development of their business, the Canadian Fairbanks-Morse Company, Limited, have had designed by Messrs. Pringle & Sons, Limited, of Montreal, a new building which will be situated at the corner of St. Antoine and St. Cecile Streets, that city. This building will be modern in every sense of the word and will be specifically laid out to adequately take care of the various departments of the business. It will have seven floors and a basement, and will be built of reinforced concrete with brick facing. An interesting feature of the building is that which makes it possible for a five-ton truck to run into the basement. The elevator equipment will consist of two freight and one passenger elevators. This building, when complete, will house the entire business, including the storage and demonstration rooms, as well as the repair shop, and will prove a very decided addition to Montreal's business buildings.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

BOOK REVIEWS:

BOOK REVIEWS.

The Gas, Petrol and Oil Engine. Volume 2. By Dugald Clerk, D.Sc., F.R.S., M.Inst.C.E., and G. A. Burls, M.Inst.C.E. Longmans, Green & Company, 39 Paternoster Row, London, Eng. 8 Vo., VII., 838 pages; 478 figures. Price, $7.50.

The name of Dugald Clerk is too intimately associated with the literature of the gas engine to require any comment, and Volume 2 of the Gas, Petrol and Oil Engine, produced in co-operation with Mr. G. A. Burls, M. Inst. C.E., is a fitting sequence to what he has previously produced. This book as a whole, will form a welcome addition to the library of anyone concerned with the development of internal combustion engines, while chapter three, dealing with igniting arrangements; seven, petrol engines; eight, some petrol engines described, and nine, on carburettors, will prove specially instructive to those interested in automobiles or motor boats.

As the authors state, Volume 1, "On the Thermodynamics of the Gas, Petrol and Oil Engine, Together with Historical Sketch" was published in 1909. The sequel to this, Volume 2, deals with practical problems of design, construction, and operation of these engines. Commencing with chapter one, the reader is shown the development of the four-stroke engine, and given the results of tests made on various types, while in chapter two a similar method is adopted with regard to two cycle engines.

Igniting arrangements are discussed under the following groups: (1) Flame method. (2) Incandescent method. (3) Methods depending on Catalytic, or chemical action. (4) Electrical methods.

Section two of this chapter treats on ignition in small, high-speed petrol motors suitable for motor cars and boats, and section three of sparking plugs.

Speed regulation, governors and governing methods are fully described.

Chapters five and six, on the various fuels used in internal engines, are more than ordinarily valuable. The various fuels are described and compared and the whole matter covered in a concise and thorough manner.

The remainder of the book deals with petrol engines, carburettors, heavy oil engines, marine gas and oil engines with an appendix on the acceleration of the reciprocating parts. The book as a whole forms a distinct addition to the literature of internal combustive engines, their fuels and accessories. The entire subject is thoroughly covered, the matter lucidly arranged, and the many tables and illustrations add much to an interesting and useful work.

The Practical Railway Spiral. With short working formulas and full tables of deflection angles, together with examples by L. C. Jordan, B.S., C.E., Principal of the Civil Engineering Department, Heffley Institute, Brooklyn, New York. Publishers, D. VanNostrand Company, New York. Illustrated; 155 pp.; 4 ins. x 6½ ins. Price, $1.50 net.

The author adopts as the rule for the close approach to the ideal in curves: Divide the spiral length into six equal parts; lay out 5 per cent. of the desired degree of curvature in the first part; in each of the next four equal parts of the spiral length attain 20 per cent. of the desired degree; and in the remaining portion of the length accomplish the remaining 15 per cent. This rule is given because of the objection to the ordinary spiral on the grounds that the grade of each rail due to run-off is curved at the ends where it joins the track grade, and that due to the play in gauge the outer wheel flange in leaving the tangent for the curve strikes a blow against the rail as it is brought against it for curvature. Whether the rail will improve the riding qualities of the track can only be determined by trial.

The tables in the book are all for the six-cord spiral for lengths of 150, 225, 300 and 450 feet. A spiral length of 150 feet for ordinary curves and 300 feet for high-speed is advocated regardless of the degree of curvature, but the method of using other chord lengths and degrees of curvature is explained on the basis of constant angles and deflections for a constant ratio of length to radius and varying angles or deflections in the ratio of length to radius when the ratio is not constant.

The author brings out in the book the present inconsistencies in the use of spiral curves on American railways, and recommends a carefully worked-out and practical spiral, as described above. It is designed on the principle of limiting the rate of tipping or run-off of elevation at the end of the circular curve to two inches per second of time, elevating the outer rail for centrifugal force to a maximum of 6 inches, and limiting the speed for the sharper curves to correspond with the length.

Apparently the author would like to standardize in practice and get away from the inconsistencies in practice of the railways, some of whom vary the length of spiral with the degree of curvature, some with the amount of super-elevation, some with the speed of the fastest trains, and some design the length of the spiral from a bending of two of the above causes.

The book, in its tendency to standardize practice in spirals is deserving of all success. We believe it will prove of interest and value to all railway engineers.

Specifications for Street Roadway Pavements. By S. Whinery. Published by the McGraw-Hill Book Company, New York. Size, 6 ins. x 9 ins.; cloth, 116 pp. Price, $1 net.

This is the second edition of this work, the original edition having been issued in 1907. The work will be found of exceedingly great interest to those who have to do with the construction and maintenance of pavements as, in addition to a large amount of information on specifications specifically, which is included in Part I. of the book, Part II., comprising 26 pages, is devoted to instructions to inspectors on street paving work and will be found of great use. Practically all types of pavements are dealt with and the specifications submitted covering these pavements will be found very valuable to city engineers and municipal authorities in general. The book contains very copious foot-notes and altogether the work is one which will be welcomed by all those interested in the question of road construction and maintenance.

Natural Rock Asphalts and Bitumens. By Arthur Danby. Publishers, Constable & Company, Limited, London, Eng. 244 pp.; 4¾ ins. x 7¼ ins.; cloth bound; illustrated. Price, $2.50 net.

The author opens with the statement that beyond the occasional articles in the technical journals and the pamphlets issued by the manufacturer, producer or seller of asphaltic materials there is no English work that is at all modern covering this subject. The book deals with the geology, history, properties and industrial applications of natural rock asphalts and bitumens, and contains a great deal of information that will appeal to any and all who have to do with the production, sale or use of these materials for any purposes whatsoever. The book goes into the geology of rock asphalts and bitumens; the sources of rock asphalt and bitumens; history and ancient uses of each of these materials; where to test and analysis, physical properties of rock asphalt. The use of rock asphalt for mastic work is given a special chapter. Altogether the work is one that is thorough, full of interest on a subject which is to many comparatively little known, and will prove exceedingly useful in making clear to many who are using these materials just what they are. The author has omitted unnecessary technicalities. Tests have been kept as simple as possible and the book should find a large sale because the subject is most ably handled. The author has clothed an otherwise dry subject with an interest that holds the reader's attention in a peculiar manner.

Transmission Line Formulae. By H. B. Dwight. Published by the D. VanNostrand Company, 25 Park Place, New York. Cloth; 137 pages; 28 figures; 17 tables. Price, $2.00.

The object of this treatise is to compile a set of instructions for engineers which will enable them to make electrical calculations for transmission lines with the least possible amount of work.

The book may be divided into two parts. The first five chapters are designed for those who have an ordinary acquaintance with alternating current calculations. The second section is for reference and contains the mathematical derivation of the formulae used in transmission line work. A transmission line regulation chart is presented for use in determining transformer regulation and efficiency.

The volume is clearly written and the formulae should prove invaluable to electrical engineers interested in transmission work.

Railroad Construction. By Charles Lee Crandall, M.C.E., and Fred Asa Barnes, M.C.E. Publishers, McGraw-Hill Book Company, New York. 321 pp.; 6 ins. x 9 ins.; cloth bound; illustrated. Price, $3.00 net.

This work, so the authors tell us in their preface, had its beginning in some notes on railroad construction which were first prepared about twenty-five years ago and issued in mimeograph form for the use of students at Cornell University.

The first chapter of the book takes up railroad construction generally and covers estimates; right-of-way; outlines of construction; clearing; shrinkage; overhaul; etc. Chapter two is devoted to earth work and contains a number of illustrations of well-known earth removing equipment, such as steam shovels, scrapers, graders, plows, dump cars, etc. Chapter three deals with the subject of rock excavating, principles of plasting, explosives, etc. Chapter four takes up the subject of tunnelling in which the various methods used in different countries are described and illustrated. Other chapters of the book cover the subjects of masonry, culvert work, foundation, track material, trestles and bridges, estimates and records. At the end of each chapter is given a table of references which will doubtless be found exceedingly useful to railroad construction engineers. There is a very full and complete cross index which forms a valuable feature of the book, as too many books are spoiled by the absence of a comprehensive and serviceable index.

Asphalt Construction for Pavements and Highways. A pocket book for engineers, contractors and inspectors. By Clifford Richardson, M.A.S.C.E., F.C.S., consulting engineer. Published by McGraw-Hill Book Company, 239 West 39th Street, New York. Size, 7 ins. x 4½ ins.; flexible binding; pp. v + 155. Price, $2.00 net.

This book, as the author states, is written with a view of supplying necessary and helpful information in regard to asphaltic concrete and asphalt broken stone pavements. It has created a demand for highway engineers, contractors, and inspectors who are schooled in this work far in excess of the supply, and the result has been that many of them do not realize the importance of careful attention to details which is necessary to insure complete success in this line of work. The author states that the pocket book has been prepared with the hope of insuring better work in the future than has been done in some cases in the past. Its form has been selected so it can be readily carried in the coat pocket for reference on all occasions.

The book is made up of seventeen chapters and an index which should be a great help in rapidly locating desired points of information. Chapters I. II. and III. are very brief, making in all a total of eight pages, and are titled: Introductory, Broken Stone, Foundation. Chapter IV. deals with "The Intermediate Course." Chapters V., VI. and VII. are on Mineral Aggregate-Filler and Dust-Native Bitumens. Chapters VIII. and IX. are on Fluxes and Cement. Chapter X. is the longest in the book, containing about fifty pages, and is on Surface Mixtures. Chapters XI., XII. and XIII. deal with Maintenance and Repair, The Plant, Work Upon the Street. Chapter XIV. is advice to engineers, contractors and inspectors, and is made up of suggestions to the above three and to citizens. Chapter XV. is upon Preparatory Work; Chapter XVI., Methods for Examination of Bituminous Materials and Mineral Aggregates; Chapter XVII. contains instructions for taking samples and specimens for examination; Chapter XVIII., reference Tables.

The book should prove very handy to contractors and inspectors and to engineers not fully posted upon asphalt pave-

ments and highways. It places simply and concisely before the reader the principles and reasons for the best highway practice and should prove very serviceable in the field for which it was intended.

Rainfall Reservoirs and Water Supply. By Sir Alexander R. Binnie, M. Inst. M.E., F.G.S., F.R.M.S., M.R.I. Publishers, Constable & Company, Limited, London, England. Size, 5¼ x 8½ ins.; cloth; 157 pp.; illustrated. Price, $2.50.

This book is founded upon the Chadwick Trust Lectures delivered by the author at the Institution of Civil Engineers in February, 1912. The object of this treatise is not so much that it might be regarded as a treatise on waterworks engineering, but more particularly to illustrate some of the salient points connected with what the author regards as one of the most difficult branches of engineering. The book deals with the questions of water and water supply in their broadest aspects, and goes into the question of the sources of supply; gravitation versus pumping; drainage areas; rivers and pumping works; aqueducts; conduits; intensity of floods; evaporation, etc. The chapter on filtration contains a number of illustrations of mechanical filters, including the Bell, the Mather and Platt, and Ransome filters. The book is fully illustrated and will doubtless prove of great interest to all students of the subject. A feature of the book which deserves a special commendation is the full cross index. It enables one to find in the minimum of time just what he wants. The book contains 56 plates and tables, and the data gathered together are drawn from various parts of the world, but particularly from Great Britain. The book will have a very special interest for Canadian engineers, in that its author was recently in Canada, having been called in company with Dr. Houston by the city of Ottawa to report on the water problem as applied to that city.

Reinforced Concrete Bridges. By Mr. Frederick Rings, M.C.I., M.S.A., C.E. (Ger. Inst.) Architect and Consulting Engineer. Published by Messrs. Constable & Company, London, England. Size, 7¾ ins. x 11 ins.; 186 pp. Price, $6.25 net.

The book is devoted specifically to the use of reinforced concrete with special reference to bridge work, and includes what to the author seems the most important features and facts the designer of bridges should be acquainted with. The bridges illustrated comprise a large variety of types common to the bridge engineer. The book discusses the advantages and disadvantages of reinforced concrete for bridge work. The question of waterproofing materials to be used, etc., is taken up in the introductory chapter. The succeeding chapters are devoted to Bending Moments, Stresses and Strains; Loads on Bridges and External Stresses; Culverts, Coverings, Tunnels, etc.; Beam Bridges; Calculation of Girder Bridges and Work Examples; Design of Arched Bridges and Abutments; Examples of Arched Bridges; etc. The work is most profusely illustrated by very excellent photos and line engravings, and will doubtless be welcomed by bridge engineers interested in reinforced concrete design and construction as a valuable addition to the literature on the subject. It contains a number of folding diagrams and from pages 158 to 181 there are a series of tables which will be found exceedingly useful to bridge engineers generally.

Rules and Regulations for Inside Electrical Installations. This is a book of rules issued by the Hydro-Electric Power Commission of Ontario and contains 129 pages. It discusses the subjects of 'installation work, wiring electric plants, grounding, maintenance and operation, and also instructions on resuscitation from electric shock. The book is illustrated and will be found of special interest to everyone who is connected with the installation or operation of electric plants of any kind whatever.

PUBLICATIONS RECEIVED.

Canadian Peat Society.—Illustrated journal issued by Canadian Peat Society, Castle Building, Ottawa, Ont.

United States Department of Agriculture.—Monthly list of publications as received by the department, Washington, D.C.

Ore Dressing and Metallurgical Laboratory.—Bulletin 160. Issued by the Mines Branch, Department of Mines, Ottawa.

Revenues and Expenses of Steam Roads for January, 1913.—Bulletin No. 50. Issued by Interstate Commerce Commission.

Annual Report of the Philadelphia Bourse.—Twenty-second annual report as presented by the directors' meeting of May 13, 1913.

Canadian Forestry Journal.—Sixty-four page journal dealing with forest conservation. Issued by the Canadian Forestry Association, Ottawa.

American Society of Mechanical Engineers.—Illustrated journal published by the society, May, 1913. Address, 29 West 39th Street, New York.

Specification of Peebles' Standard Turbo Alternators.—Specifications of alternators. Issued by Bruce, Peebles & Company, Limited, Edinburgh.

Mine Inspector of the Territory of Alaska.—Report of mine inspector for the fiscal year. Issued by the Department of the Interior, Washington, D.C.

Forest Service Investigations.—Illustrated review of the work conducted by the Forest Service; issued by Henry S. Graves, United States Department of Agriculture.

Patents.—Illustrated official journal of patents of Great Britain, April 9, 1913. Issued by the Patent Office, Southampton Building, Chancery Lane, London, W.C. Price, 6d.

Forest Conditions.—Illustrated bulletin issued by T. W. Dwight, M.F., Department of the Interior, Canada, on forest conditions in the Rocky Mountains forest reserve.

Selection of Explosives.—Illustrated bulletin on the selection of explosives used in engineering and mining operations. Issued by the Department of the Interior, Bureau of Mines, Washington, D.C.

American Railway and Bridge Building Association.—Proceedings of the 22nd Annual Convention, held at Baltimore, October, 1912. 9 ins. x 6 ins.; 295 pp.; numerous illustrations. Price, $1. Apply C. A. Lichty, secretary, 26 West Jackson Boulevard, Chicago, Ill.

Good Roads.—Hearings before the Joint Committee in the Construction of Post Roads, January 21st, 1913. Part I.; 9 ins. x 6 ins.; 220 pp. Apply A. W. Prescott, secretary, Joint Committee on Federal Aid in the Construction of Post Roads, Washington, D.C.

Tests of Reinforced Concrete Buildings Under Load.—An interesting, illustrated bulletin on the tests of three large buildings, by A. W. Talbot and W. A. Slates. Copies may be obtained from the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

Report on the Tractions Improvement and Development of the Toronto Metropolitan District.—A most exhaustive report taking in all phases of transportation as it affects Toronto and outlying districts. The text of the report covers present traffic conditions; car lines recommended; cars and service requirements; costs and returns. Contains twenty-six photographs and drawings. Forty-eight 6 x 9 ins. pages.

Reconnaissance Along the National Transcontinental Railway in Southern Quebec.—Interesting booklet written by John A. Dresser and published by the Department of Mines. Deals with the general geology, description of land formations and topographical character of the Laurentian and Appalachian highlands and the St. Lawrence lowlands.

The Concrete House and Its Construction.—A practical working volume containing important details involved in the construction of concrete dwellings. Nicely illustrated, showing interior and exterior views of noted concrete houses. Issued by the Association of American Portland Cement Manufacturers, Land Title Building, Philadelphia, Pa.

Producer-Gas Power Plant in the United States.—By R. H. Fernaed. Is a nicely illustrated bulletin dealing with the present status of the producer-gas power plant, fuel-testing, blast-furnace and coke-oven gas plants. Also the views of manufacturers, owners and operators of producer-gas plants, and has attached map showing graphic distribution of producer-gas plants in the United States. Issued by the Department of the Interior, Bureau of Mines, Washington, D.C.

The Reading Iron Company, of Reading, Penn., send us Bulletin No. 10, which is devoted to an illustrated description of the Illmer gas engine, which engine possesses a number of new features. The engine is intended primarily for driving electric generators, pumps, rolling mills and other heavy duty service operating at a reasonable load factor. To those interested in the subject we would strongly advise them to send for a copy of this bulletin and we are sure it would be gladly sent by the manufacturers.

Bulletin of Revenues and Expenses of Steam Roads in the United States.—This is a pamphlet prepared by the division of statistics and covers the revenues and expenses of railways during the month of February, said railways reporting to the Interstate Commerce Commission. In the bulletin will be found operating revenues and expenses of large railways and their principal subsidiaries showing whose total operating expenses exceed one million dollars. The pamphlet contains 36 pages, 9 ins. x 12 ins.

Torquay Water Undertaking.—This is an illustrated description of the new filtration plant at Torquay. Issued by the Candy Filter Company, Limited, of London, by which firm the installation was carried out. The plant has a capacity of two and a half million gallons per day and the sketch of the work done is written by Samuel C. Chapman, water engineer of the municipality of Torquay. The pamphlet contains twelve pages, one half-tone illustration and two diagrams, one showing the layout of the filters and the other a cross section.

Good Roads.—Tables showing in condensed form for ready reference and comparison, data regarding the highway systems of the leading nations of the world and statistics bearing upon federal aid in highway improvement in the United States. Compiled by the Hon. J. Bourne, Jr., chairman of the joint committee on federal aid in the construction of roads for the United States Congress. Revised print, March 20th, 1913. 12 ins. x 9 ins.; seven folded charts. Apply A. W. Prescott, secretary, Joint Committee on Federal Aid in the Construction of Post Roads, Washington, D.C.

Expert Evidence.—Verbatim report of a discussion held at a meeting of the American Institute of Consulting Engineers, Eugene W. Stern, secretary.

A most exhaustive discussion on the subject referred to above is contained in the fifty-eight pages of the pamphlet and will well repay any engineer who may have the privilege of reading the same. In as much as there is a good deal of opposition to the present methods of securing expert evidence in legal cases, it is an exceedingly interesting subject, and one that is of great importance to the engineering profession. The following well-known engineers took part in the discussion: Mr. Rudolph Hering, Mr. Gustav Lindenthal, Mr. Cary T. Hutchinson, Mr. L. B. Stillwell, Mr. Sanford Thompson, Mr. Frank H. Waterman, Mr. Livingston Gifford, Mr. Alfred Noble, and Mr. E. W. Harrison.

The discussion was full of information that should be brought to the attention of every engineer who is likely to be called upon to give expert evidence where cases are before the courts, and where engineering knowledge is needed. It makes good reading.

CATALOGUES RECEIVED.

All Famous.—Illustrated pamphlet, 10 pages. Issued by the Heine Safety Boiler Company, St. Louis, Mo.

The Universal Crane and Excavator.—Illustrated catalogue; 15 pages. Issued by the C. O. Bartlett & Snow Co., Cleveland, Ohio.

American Vanadium Facts.—Illustrated catalogue published by the American Vanadium Company, 341 Vanadium Building, Pittsburgh, Pa.

The Hardy Simplex Hammer Drills.—Illustrated catalogue showing three types of drills. Issued by Mussens, Limited, 318 St. James Street, Montreal.

Blacksmithing and Drop Forging.—Illustrated bulletin dealing particularly with heavy forgings. Issued gratis by the Tate-Jones & Company, Inc., Pittsburg, Pa.

Bayer Railway Speed Recorder.—Illustrated catalogue, giving description and instruction for applying and operating recorder. Issued by the Chicago Pneumatic Tool Co., Fisher Building, Chicago.

The United States Graphite Company's Products.—Illustrated catalogue issued by the United States Graphite Company, Saginaw, Mich. Deals with the company's graphite products and is intended to serve the trade as a convenient reference.

The B. Greening Wire Company, Limited, of Hamilton, send us a copy of their catalogue which contains a very full and complete illustrated description of their various specialties. It also contains an historical sketch of the business which was started 'way back in 1858. The catalogue contains 228 pages, is fully indexed, and contains among many other things a number of interesting tables which will be of interest to all those who use wire goods of any description.

Text Book on Corrosion.—An interesting bulletin published by the Stark Rolling Mill Company, of Canton, Ohio, sole producers of Toncan metal. Contains interesting technical information on the introduction of mild steel, rust and corrosion, chemical electrolysis, conservation of metals, efficiency, elimination of corrosion, and value of galvanizing steel. Is nicely illustrated, showing prominent installations of Toncan metal, and is a complete compendium of all necessary information in reference to sheet metal.

The Great Market Street Paving Contract is the title of on interesting booklet issued by the United States Wood Preserving Company. Copies will be sent to interested persons on request by the Canada Creosoting Company, Canadian Pacific Building, 1 King Street East, Toronto. The booklet tells how the Market Street Merchants' Association of Philadelphia, Pa., decided to use wood block when they investigated the problem of repaving Market Street after the street had been torn up for the construction of a subway. The report of the committee and a report by a firm of paving chemists, newspaper clippings, illustrations of streets, etc., are included.

COAST TO COAST.

Toronto, Ont.—Chief Engineer F. A. Gaby, of the Ontario Hydro-Electric Commission, reached this city after a five months' flying tour of the continent. His mission, which was to gather electrical data towards the more efficient operation of a power and lighting system, he claims was very profitable. Much technical information dealing with power production was gathered and this will be embodied in a report for submission to the commission. "Ontario leads in transmission lines," was the comment he made on the problem of distribution. He told of a scheme closely resembling that of the province which had been formed in Sweden and was now on a running basis. The same ideas of carrying power to homes and farms were used, but whereas in some ways their operation was an improvement, he declared that the transmission line system here outclassed any he had seen. He stated that little public ownership on a large scale was apparent, but that several thriving cities, especially in Germany, managed their own systems. France, Germany, Switzerland, Holland, Sweden and England were visited and their leading electrical plants inspected.

Toronto, Ont.—The good roads programme of York county was brought before the Ontario cabinet recently and is at the present time obtaining consideration. After the usual system by which the government advances one-third of the amount raised by the city and county, the $300,000 voted two years ago has been expended. Now, in view of the plans of the government as to a broader policy for old Ontario, it is a question how far roadways should proceed under the old standard. York county, which was represented by Lionel H. Clark and Engineer James, has voted for additional expenditure, and seeink ratification from the minister of public works, the best method to pursue under the circumstances is being debated in cabinet. It is understood that if the present plan goes through, the sum of $100,000 will be asked of the government.

Montreal, Que.—That the $2,000,000 floating drydock placed here last fall is likely to prove to be a white elephant is confessed by shipping authorities. It was thought that shipowners would use the dock for all repairs needed by vessels, but it has been found that no company will put a ship in the dock while there is the slightest chance of sending it to British ports for repairs. A case in point is that of the Elder-Dempster steamer "Benguelo," which will get a much-required scraping when she gets to South Africa, where the work can be done by cheap black labor. As the shipping companies are getting cheaper insurance by reason of the dock being here, it is suggested that while they will not use it, they are not entitled to the advantage and that it should be taken to Quebec.

Victoria, B.C.—Arrangements are in view for a thorough investigation of the water supply of Victoria as derived from Elk Lake, the examination to be made of water from points both at the entrance and exit of the filter beds at Beaver Lake. Until recently only chemical analyses were possible. While these tests are sufficient to detect any organic impurities, it has been impossible, until the city possessed a laboratory where bacteriological experiments were possible, to know what amount of bacteria was passing through the sand, and in fact, to what extent the filter beds were discharging their office. When these tests have been made it will be possible to determine whether the sand is effective, and what percentage bacteria is detained in the beds in process of filtration. A series of systematic tests is proposed by the city analyst on behalf of the water commissioner.

Vancouver, B.C.—Vancouver has lost more than $450,000 in business this year through not having a commercial drydock, but two groups of engineers and financial men are arranging to supply the need, according to statements made recently at the meeting of the Board of Trade in connection with report given upon the recent visit to Ottawa of Mayor Baxter and Mr. W. A. Blair, secretary to the board. Mr. Blair gave statistics regarding boat repair work which went to Esquimalt and Seattle the first three months of the year, but which, in his opinion, would have come to Vancouver had there been a drydock here. Six passenger boats which call at Vancouver had gone to Esquimalt for repairs totalling $226,000, and $75,000 had been expended there upon smaller craft. Seattle has obtained $150,000 through work on other boats which call here. Mr. Blair prefaced his report by the statement that the delegation did not go to Ottawa to form a company to build a dock, but to strengthen the hand of Mr. H. H. Stevens, M.P., in presenting the claims of the city for the establishment of a drydock and a grain elevator. After citing his figures with reference to the loss of business to Vancouver, he said the delegation was informed no naval dock would be built for several years, and the delegation then devoted attention to the question of the commercial dock. As a result they obtained assurance that the drydock subsidy would be changed to favor the financing of such an enterprise. Change of the Act will not be made until next session, but if a bona fide company makes a proper showing the interest will be increased by an order-in-council to 4 per cent. on $6,000,000 for thirty-five years on progressive estimates, and the action ratified by legislation. Mr. Blair said he had good reason to believe that a drydock would be built soon, and that it would be a credit to the promoters and to the city. Mayor Baxter said that since his return representatives of two groups considering the building of a dock had been in conference with him.

Ottawa, Ont.—The Board of Railway Commissioners, being impressed with the large number of accidents occurring at level railway crossings (crossings of one railway by another) which are not protected by signal system with or without derails approved by the board, are asking that railway companies subject to the jurisdiction of the board, show cause, in writing, within thirty days, why an order should not issue requiring such railway companies to install and complete, within three years from date of such order, an interlocking system to be approved of by the board for the protection of all level crossings which are not so protected between tracks of steam railways and between tracks of steam and electric railways.

Peterborough, Ont.—City Engineer Parsons has returned from Toronto, where he went to look into the sewage disposal question respecting Peterborough. Mr. Parsons waited upon Dr. McCullough, chief of the provincial board of health for Ontario, and ascertained the latter's views regarding a suitable plant for this city. The provincial board of health favor the use of Imhoff tanks either with the treatment of the effluent by chlorination, or by sprinkling or intermittent filters. The scheme will have to be worked out with a view of determining the probable cost, not only the first cost, but also the question of maintenance. Mr. Parsons also visited the Toronto engineering department, but was unable to obtain anything that would be applicable to Peterborough. The next move will be to prepare plans and submit them to the provincial board of health engineers for their approval.

Vancouver, B.C.—Preliminary work for the construction of the Georgia-Harris viaduct is rapidly progressing to a point where citizens can readily observe tangible indications of a prompt completion of the project. The contractor already is receiving on the ground the lumber for constructing the form work for the superstructure at the Harris Street

end. The steel shoes for the six concrete caissons to be sunk in False Creek are expected to arrive soon, and plans have been devised for sinking the large cylinder down to hard pan. All of the thirty-six footings in Harris Street, from Main Street to False Creek are in place. Some of the footings have been sunk to a depth of fifteen feet and the steel for the remainder of the footings has been delivered on the job. The excavation has begun for the retaining wall at the foot of Georgia Street, and for the various piers through the Canadian Pacific Railroad property. The sinking of the cylindrical caissons, 12 feet in diameter and 40 feet long, will be started as soon as the steel shoes now in transit arrive. The concrete cylinders will be eight inches thick. The steel ties and tracks will be laid in the concrete as it is poured for the various sections. The viaduct, of concrete construction of the Turner mushroom system, will be 2,880 feet long, sixty-six feet wide, and will carry a 53-foot roadway having double tracks in the centre. Various electrical conduits will cross the structure which will be erected along the outer edge, which will be provided with six-foot walks. Massive concrete railings will be erected along the outer edges, which will be provided with 54 ornamental lamp standards of fluted columns made of concrete.

Victoria, B.C.—"Battleships versus Good Roads" would be a good topic for debate among certain enthusiasts for improved highways in the United States, according to George E. Daniels, the well-known authority on automobiles, who has some very decided views on the comparative advantages of well-constructed highways over huge navies, and it is his opinion that greater benefit to the country at large can be obtained through a good roads movement than through a plan to increase the equipment of the navy. "I am perfectly sincere," says Mr. Daniels, "in declaring my preference for the good roads propaganda over the agitation for more vessels of war. I believe that the American Congress, instead of increasing the naval appropriation for the sake of building up a large navy, should spend these millions on national turnpikes. It seems to me there is sound reason for this preference. There is no greater factor in the creation of progress and prosperity affecting our people at large than good roads. It would be silly to assert that good roads are merely to increase the pleasure of a favored few. There is nothing that has a greater economic significance than roads well maintained, for they open up the country so that its fullest commercial development is possible. Moreover, they are the arteries of civilization and without them whole districts stagnate. In this connection they have a distinct ethical value. In general they promote the peace, prosperity and happiness of a country and should therefore receive consideration long before we consider increasing our naval prestige. It is rather humiliating to think that the old countries of Europe, so far behind us in many ways, have learned this and appreciate good roads. When it comes to highways, we are sadly behind Europe, as anyone who has travelled abroad and also through our own states knows full well. It seems curious that we who are such a practical people and presumably so keen for progress and material success should so flagrantly neglect this great factor. Therefore, I say, the time is at hand to boost the good roads movement."

Winnipeg, Man.—Providing the engineering problem is feasible and the cost not too great, Shoal Lake will be the source of supply of the Greater Winnipeg water district. A large majority of the members of the city council attended a meeting of the fire, water and light committee held recently, and after hearing a very satisfactory report on Shoal Lake water from the three consulting engineers, it was unanimously decided that the consulting experts should not be asked to go to Winnipeg River, but that if it is found advisable, they may later be asked to make a supplementary report on the Winnipeg River from data contained in existing reports. The question of filtration of Shoal Lake water was raised by all three of the experts who explained that while it was by no means necessary it might be regarded by the citizens as advisable. They made it plain that Shoal Lake water is pure and soft, and from the hygienic standpoint absolutely clean, but they explained that suspended vegetable matter might cause a slight taste or smell. Engineer Fuertes declared that Shoal Lake water is better than New York has used for 20 years. The members of council lost no time in deciding that there would be no filtration in the meantime and that Shoal lake water is quite good enough as it is. The formal motion, put forward by Controller Midwinter, read: "That the board of consulting engineers be instructed to report on the best means of supplying the Greater Winnipeg water district with Shoal Lake water, with estimate of cost and general plan of work." At the same time it was agreed that should the report not prove as favorable as is anticipated, the engineers should later make a supplementary statement on the feasibility and cost of a supply from the Winnipeg River. Mr. J. H. Fuertes, New York; Frederick P. Stearns, of Boston, and Mr. Hering, are the consulting engineers.

PERSONAL.

R. HUNTER, assistant engineer of the Beach pumping station, at Hamilton, Ont., has resigned to take up a position at Welland, Ont.

DR. JAMES DOUGLAS, of New York, graduate of Queen's, has sent Dean Goodwin a cheque for $25,000 for the establishment of tutorship in the School of Mining.

W. H. RANDALL, superintendent of the waterworks maintenance and distribution of Toronto, will attend the annual meeting of the American Waterworks Association, which meets in Minneapolis, Minnesota, from June 23 to 26.

MR. H. A. DONOVAN, who has been connected with the electrical department of the Winnipeg Electric Railway Company, of Winnipeg, Canada, has been appointed assistant electrical engineer of the company, succeeding Mr. E. A. Graham, resigned.

MR. D. R. KENNEDY, electrical superintendent of the British Columbia Electric Railway Company, of Vancouver, B.C., has resigned his position, and Mr. W. H. Fraser, who has been connected with the electrical staff of the company, has been appointed in his place. Mr. Kennedy will spend the next few months travelling through the States and the Dominion, inspecting various electrical plants.

MR. D. McD. CAMPBELL, city engineer of Sydney, N.S., has resigned. Mr. Campbell entered the service of the city as a member of the city engineer's department in 1900, and was appointed to the position of city engineer in 1908. It is understood that Mr. Campbell is to engage in private practice as a consulting engineer. The board of works of the city of Sydney accepted his resignation with a good deal of regret and so expressed themselves.

ARCHIBALD CURRIE, C.E., graduate of Glasgow University, and member of the Institute of Civil Engineers of London, Eng., at present city engineer of Westmount, Que., has been appointed city engineer of Ottawa. Mr. Currie has had a wide experience, holding positions in Scotland, England, China (during the Boxer trouble), and South Africa. He has been city engineer of Westmount since 1911, and has given general satisfaction since his appointment. He will commence his duties at Ottawa on June 20.

CAPTAIN A. W. GRAY, assistant highways commissioner of Ontario, has been appointed highways commissioner

for the parks branch of the Department of Interior, Ottawa. The position is a newly created one and the object of the government is to establish a series of fine highways through the public parks of the west for automobiles and for horses. Captain Gray is an engineer of high standing and has had many years of experience in the work of highways construction. He is an expert in his particular line and the appointment is regarded as an excellent one. He will probably make his headquarters in Edmonton, Alta.

OBITUARY.

ARCHIBALD GUTHRIE, prominent railway contractor, died May 18th, at Chicago, following an operation. Deceased was 77 years old and was born at Lanark, Ont., and received his education there, entering the contracting business, and at the time of his death was senior member of the firm of A. Guthrie & Company. He gained distinction in early northwest railway extension, and carried to completion some of the most pretentions plans in railroad building in the country.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE CANADIAN FORESTRY ASSOCIATION.—National Convention will be held in Winnipeg, Man., July 7-9. James Lawler, Secretary, Canadian Forestry Association, Canadian Building, Ottawa.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held at Chicago, Ill., Feb. 16-20, 1914. Secretary, E. E. Kraus, Harrison Bld., Philadelphia, Pa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—176 Mansfield Avenue, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—

177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, A. B. Lambe, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, P. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 534 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSIOCATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Edmund Burke; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

TECHNOLOGY CLUB OF LOWER CANADA.—President, F. E. Came; Secretary-Treasurer, E. B. Evans. Meets twice yearly.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

TERMINAL PASSENGER STATIONS; THEIR DESIGN AND OPERATION.

By J. L. BUSFIELD, B.Sc., A.C.G.I.

(Continued from last issue.)

Another interesting feature which is quite prevalent in British railway terminals is the cab and carriage driveway between the two inbound platforms. This enables passengers to step right from the train to the cabs and carriages without any delay. The platform may also be reached by means of stairways from a footbridge in the middle of the station. The baggage is handled from the baggage room to the train platforms by means of subways and elevators.

The American Railway Engineering Association have designed a typical track layout suitable for a dead-end station of medium size. This layout is illustrated in Fig. 5, and it is of interest to look into the general requirements and conditions met with in a terminal of this type.

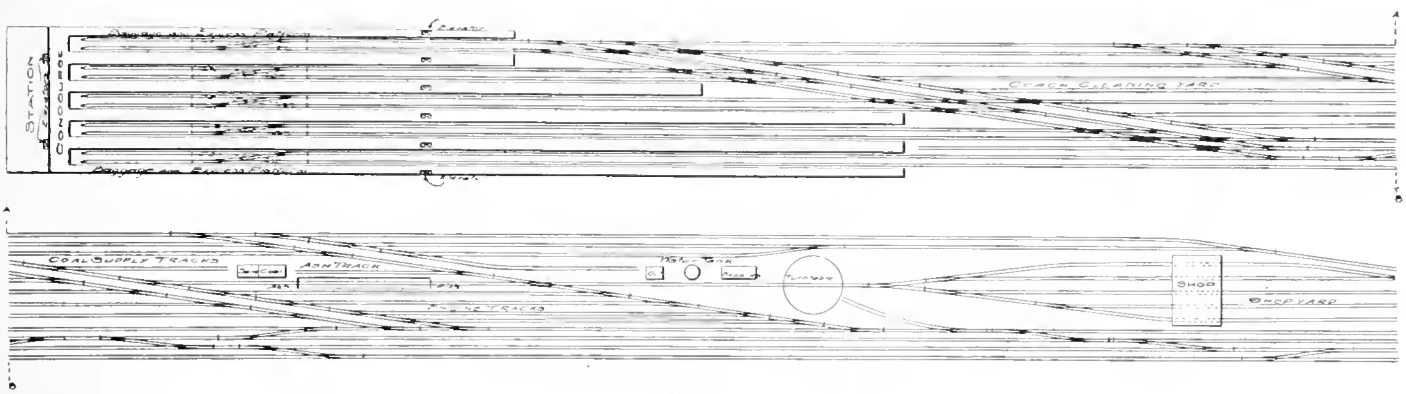

Fig. 5.—Typical Dead-End Terminal.

In order to secure the maximum efficiency of tracks and facilities and the minimum installation expense, the terminal facilities must be designed so as to provide such an arrangement of tracks and platforms that will permit the greatest freedom of movement with the least interference, so that incoming and outgoing trains may be handled without delay.

In most terminal stations facilities have to be provided for hauling the majority of the trains out of the station proper and placing them in a special cleaning yard, and frequently after they have been cleaned they have to be placed in a storage yard, previous to their being placed in the train shed ready for the outgoing journey.

It is sometimes necessary to arrange for trains at a terminal to arrive and depart in rapid succession, and it is in this case that great care must be taken in designing the track layout so that there will be the minimum of interference between the inbound and outbound movements. If the track layout is properly designed it will be possible in many cases to permit trains to enter the station at the same time as other trains are leaving and to fill vacant tracks with the least delay. This will insure maximum efficiency and a minimum of installation cost.

The number of trains that can be handled at a platform or, in other words, the track capacity, depends largely on the rapidity with which the baggage and express can be handled while the train is at the platform, so that in order to have the maximum number of trains operated on the minimum number of tracks the baggage and express handling facilities must be the best possible, and arranged to give the minimum amount of interference to the movement of passengers. This feature is best obtained by handling all the baggage and express either below or above the train floor and transferring it to the platforms by elevators. This method eliminates the annoyance and discomfort to passengers which results from trucks on long and busy platforms.

The time required to handle a train in the terminal, i.e., to load and unload passengers, baggage and express, depends largely on the nature of the train, as it takes longer to put the baggage and express on to a main line train than it takes the passengers to embark, while in the case of a local train the conditions are exactly reversed, but is has been found that the number of trains that can be conveniently handled per hour per track varies from two for main line trains up to a maximum of eight for locals, with an average of 4.1 trains per hour. These averages were obtained from a number of large terminals, but they are naturally liable to large variations, depending on the nature of the traffic.

If facilities are provided for the continuous and rapid handling of baggage and express without interfering with passengers it is believed that a terminal can be operated with such efficiency as to give an average of 6.5 trains per hour. In order to obtain this high efficiency, the track layout and all facilities must be designed with this object of saving time.

In the plan shown in Fig. 5, representing a typical dead-end station, with eight platform tracks, it will be noted that the double-track arrangement is preserved at the entrance to the train shed in such a way as to give practically continuous use of the platforms and tracks. This double-track arrangement is only made possible by the use of slip-switch cross-overs which allow a train to keep to its own right-hand track until it reaches the outer end of the platform to which it is assigned. Similarly a train can arrive at outermost platform at the same time and without interference from an outgoing train from any of the other platforms. With the old layout of a single ladder, the incoming train would have to wait at the throat of the yard until the outgoing train had passed on to its own main line track.

In connection with this typical plan of a dead-end station, the committee of the American Railway Engineering Association came to the following conclusions:

"(1) To avoid excessive cost in providing passenger terminal facilities largely in excess of ordinary requirements, it is imperative that provision be made for the economical, efficient, and practically continuous operation of the terminal during the periods of greatest activity, which may reasonably be expected within a period of, say, twenty years. To this end the track layout may be designed to permit incoming and outgoing movements to be made at the same time without interference as far as possible to arrange this."

"(2) At passenger terminals where large quantities of baggage and express must be handled, and it does not appear expedient to use intermediate platforms exclusively for this service, it is recommended that (where conditions permit) baggage and express be received, delivered and handled below the train floor and raised and lowered by elevators, conveniently located, to avoid interference with the movement of passengers."

The plan in Fig. 5 shows, in addition to the train shed trackage and platform arrangements, typical recommended arrangements for the coach yards for storage and cleaning, etc. These are only incidental to the general scheme, as in most cases the layout and location depend entirely on local conditions.

The design and layout of a terminal passenger station of the through type is a very different subject to that of a dead-end terminal. The through terminal can be more economically and efficiently built and operated than a dead-end terminal, as the number of platforms required to handle a certain volume of business is less in a through terminal, because trains can be handled in and out very much more rapidly. There are practically two types of through terminals proper, namely, those with the station building to one side of the tracks, and those with the building built over, or above the level of the tracks.

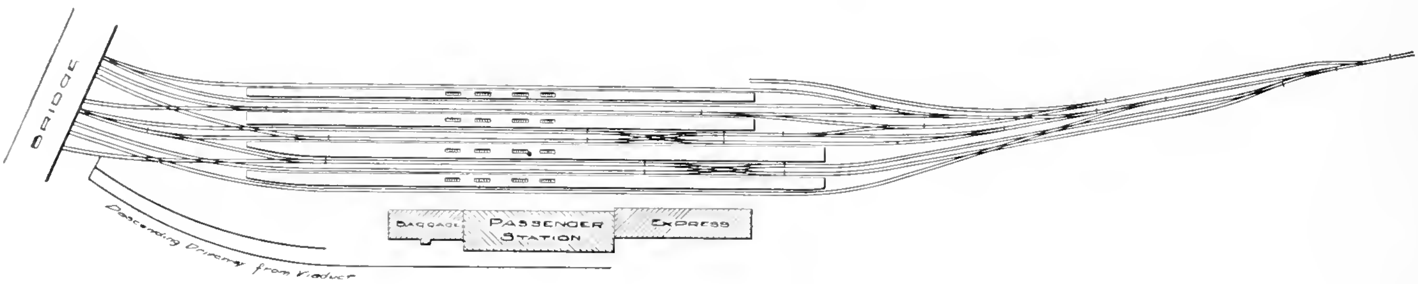

Fig. 6.—Union Station, Columbus, Ohio.

A large terminal of the through type is the Columbus Union Station owned by the Pittsburg, Cincinnati, Chicago & St. Louis Railway, and by the Cleveland, Cincinnati, Chicago & St. Louis Railway jointly. There are in all six railway companies using this terminal. The general layout is shown in Fig. 6. There are four platforms, three 17 feet wide and one 11 feet wide. Two are 678 feet long and the other two have been extended to a length of 774 feet. These platforms are all 8 inches above the top of the rails. The tracks in pairs are spaced at 11 feet centres and the edge of the platform is placed 5 feet ¾ inch from the centre of the track. The tracks are all below the street level.

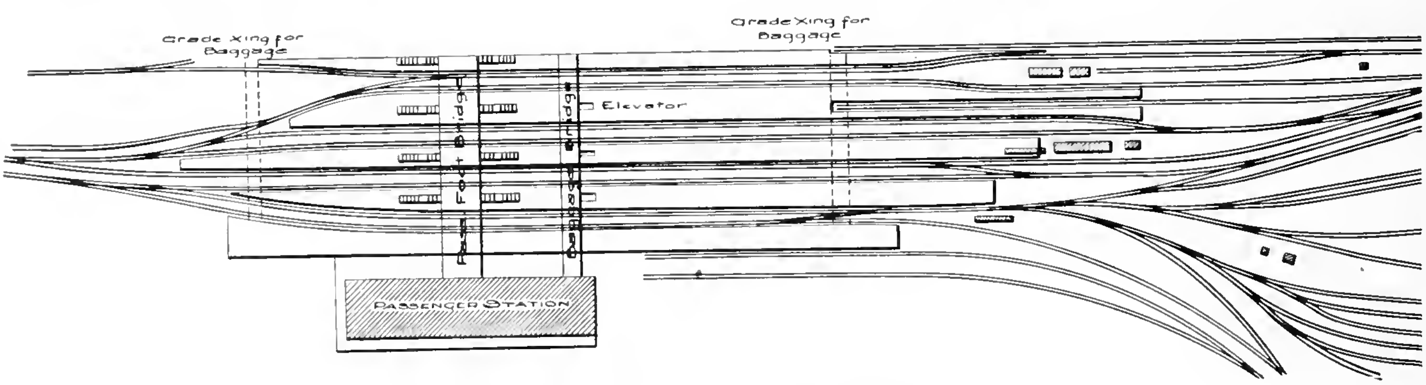

Fig. 7.—Harrisburg, Pa., Pennsylvania Railroad.

The front entrance and general waiting room are all on the street level. The passengers reach the platforms from the general waiting room by means of an overhead bridge extending across all the tracks, from which stairways lead down to the platforms. There are also stairways from the platforms down to a subway below the tracks which connects with the basement of the station. This subway is only used for rush business. The baggage and express rooms are on

the basement floor, the baggage between the waiting room floor and the basement being handled by means of elevators.

There are 51 through trains, 34 originating and 35 terminating trains handled at this station per diem. The trains terminating are broken up with yard engines and each tenant company has its own engines which take its train to its own separate sorting and storage yard.

Another large through terminal is that of the Pennsylvania Railroad at Harrisburg, Pa. (Fig. 7). At this station there are 52 through trains, 47 originating and 45 terminating per day, and practically all of these are through main line trains, as there is very little suburban business. This station is a terminal of four divisions of the Pennsylvania Railroad and of the Cumberland Valley Railroad, the latter having independent stub tracks. Engines are changed on all through trains here; cars are frequently added to or taken from the trains. The switches are all operated by means of an interlocking plant.

There are four pairs of tracks placed at 12 feet 2½ inches centres, with platforms between each pair. Two of these platforms are 22 feet wide, and the remaining ones are 15.8 feet, 33.9 feet and 37 feet in width, with lengths of 765 feet to 850 feet. The platforms are reached by means of stairways and an overhead bridge at the waiting room level.

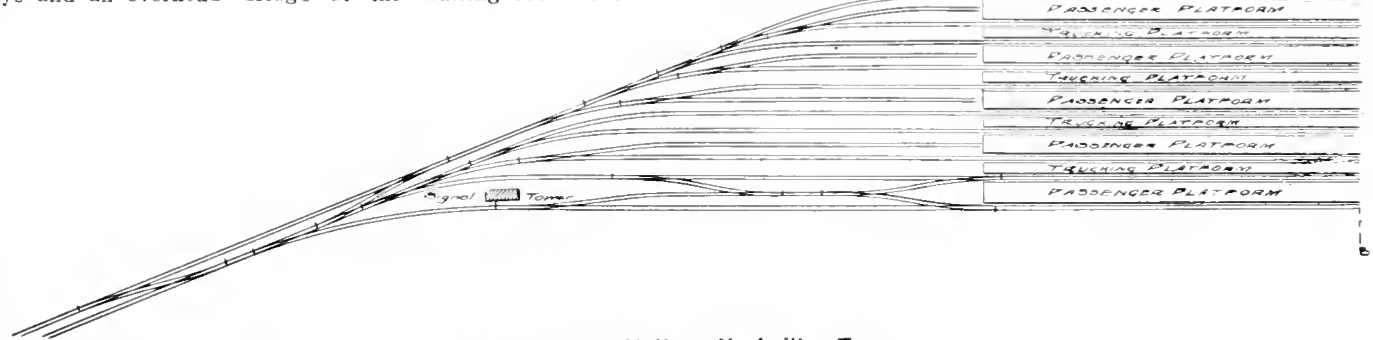

Fig. 8.—Union Station, Nashville, Tenn.

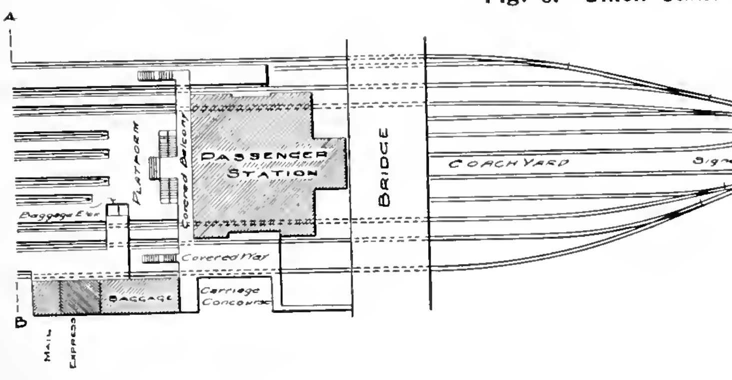

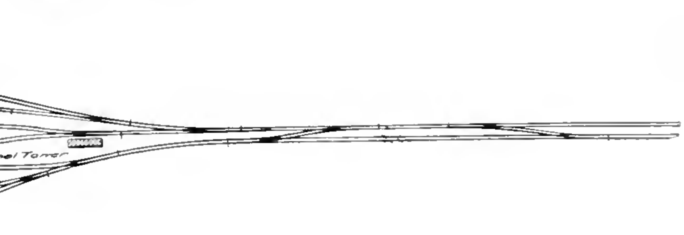

Another overhead bridge is provided for the baggage and express service, the trucks being lowered to the platforms by means of elevators.

The engine house at this terminal is about ¾ mile away from the station and the car storage yard is about 650 feet west of the station yard. The cars are handled between the engines and the storage yard by switching engine.

Another type of terminal commonly met with is the combined through and dead-end terminal, having a number of stub tracks and also a number of through tracks. A typical example of this kind is illustrated in Fig. 8, showing the layout of the Union Station at Nashville, Tenn., owned by the Louisville and Nashville Terminal Company and leased to the Louisville and Nashville Railway and the Nashville, Chattanooga & St. Louis Railway jointly.

There are 10 through and 26 originating and 26 terminating main line trains daily and no suburban trains. A certain amount of switching and making-up of the through trains is done, putting on and taking off Pullmans, etc.

There are six through tracks and four stub tracks in this terminal, spaced alternately 20 feet and 28 feet between centres, except where the train shed columns are situated on the platforms, where the spacing is 34 feet. The platforms are divided into passenger and trucking platforms, the former being 20 feet wide and the latter only 11 feet. They vary in length from 550 feet to 750 feet and are 9½ inches above the rails.

The engine house is over ½ mile away from the station and the car storage yards are over ¼ mile away. All the trains are handled and made up in the terminal and yards by switch engines.

The station building itself is placed at the end of the stub tracks and the through tracks pass to either side of the station, except one which passes through the lower part of the building.

The waiting rooms and general accommodation in the station is on the street level, above the tracks, and the passengers reach the platform from a balcony with stairways to the platforms and to a concourse at the end of the stub tracks.

These terminals described above will give a general idea of standard practices with regard to the different kind of passenger terminals, but at some of the more recent and larger terminals, such as the New York Central's Grand Central Station in New York, certain improvements have been introduced.

There are a number of problems, however, which the designer has to solve apart from difficulties due to the local conditions. For instance, he has to decide on the relative merits of handling baggage through subways and elevating to the platforms, or handling the trucks on special trucking platforms (as at the Nashville Union Station) reserved solely for this purpose, or as is more commonly done in the older terminals, to have the regular platforms wide enough to enable the baggage to be handled in the same platform as the passengers without causing inconvenience and delay either to the passengers or to the baggagemen.

The track layout at a terminal has been given much more serious consideration in recent years than formerly, with the result that the double ladder has been developed.

in order to bring the double track to each platform, so as to give great flexibility of movement and almost unlimited capacity for handling suburban traffic with electric trains.

Another phase of station design which is being brought into general use now is the elimination of stairways, and the substitution of inclined ramps between the different levels of the station, waiting rooms, platforms, subways, etc. In many cases, on account of limited space, the use of ramps becomes impossible, but where they have been put into service they have proved very satisfactory.

At the Grand Central Terminal, New York, while the alterations were being made experimental ramps at different grades were built in order to find out what grade the public preferred to take; it was found that the ramp with a grade of 8 per cent. was most popular. However, it is not always possible to use such a flat grade as this, but it should not be steeper than 10 per cent.

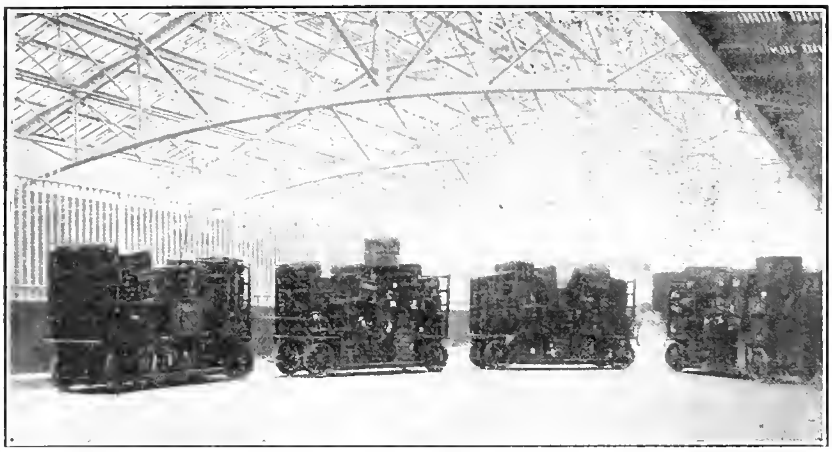

Fig. 10.—Drop Frame Electric Baggage Trucks.

A terminal where these modern ideas have been put into effect is that of the New York, New Haven & Hartford Railway, at Providence, R.I. The structure is substantial and pleasing to the eye, the driveway and approach is covered in. At the rear of the station building is the train shed with a concourse intervening. There are eight through tracks and the intermediate platforms are reached by subways and ramps. Another feature of this station worthy of special mention is the large and commodious toilet room accommodation which, unlike many stations, is provided with plenty of daylight and good ventilation.

Fig. 9.—Pennsylvania Electric Baggage Truck.

The description of passenger terminals would be incomplete without a reference to the use of storage battery electric motor trucks for handling baggage and express. The Pennsylvania Railroad was one of the first to see the possibilities of this type of truck and commenced experimenting with them as early as 1904, but it was not until 1910 that they actually commenced to use them. It was also about this time that the New York Central Line commenced installing them.

Twelve trucks were first put into service by the Pennsylvania Railroad at their Jersey City terminal in 1910. These trucks were 12 feet long and 44 inches wide, with the platform 30 inches above the ground. This truck is illustrated in Fig. 9. The frames were of all steel construction, the ends were of pressed steel. Both pairs of wheels were mounted with knuckled axles and the steering gear so connected that all four wheels were utilized for steering, thus enabling the truck to turn in a very confined space. This feature, though, was not entirely necessary because the trucks are arranged so that they can be operated from either end. The steering and controlling gears are linked up to duplicate lever sockets at either end of the truck, so placed that when not in use the sockets do not project beyond the ends of the trucks. The handles cannot be removed whilst the truck is in motion. The operators' platforms are hinged and connected so that they cannot both be down in running position at the same time, but if necessary they can both be placed vertically against the ends.

The motive power of these trucks is an Elwell Parker motor, which is flexibly suspended so as to oscillate about the counter-shaft. The requisite speed of the driving wheels is obtained by a double reduction gear through a countershaft. The pinion on the countershaft is connected to it with a universal joint to allow for the turning of the driving wheels. This pinion drives on to an annular gear rigidly fixed to the driving wheel.

The wheels are of the artillery type, 27 inches diameter, one pair of wheels has the annular gear for the drive and the other pair are fitted with internal expansion brakes.

The battery on these trucks is of 12 cells, capable of giving 196 amp. hours, and is placed on a tray suspended on compression springs. The controller gives three speeds in both directions, the two running speeds giving four to five miles per hour and five to seven units per hour respectively. The weight of the truck is 2,390 lbs. and it has a capacity of 4,000 lbs.

The Elwell Parker Company, of Chicago, Ill., are now manufacturing two types of these baggage trucks, one is the straight frame type and is practically identical with the one originally built by the Pennsylvania and illustrated in Fig. 9. The other type they are now building is the drop frame type illustrated in Fig. 10. This truck has the centre part of the platform dropped down to within a few inches of the station platform. This truck was designed for especial use in terminals where the platforms are placed at the height of the car floors.

At one large terminal exhaustive tests were made with these trucks comparing them with hand trucks. For mail handling it was found that one electric truck operated by one man would equal the performance of 2½ hand trucks and five men, based on the full capacity of the trucks, viz.,

two tons for electric and one ton for the hand truck. For baggage handling, two hand trucks were equivalent to one electric. Actual figures with the hand truck as a basis were obtained as follows:—

	Electric Truck.		Hand Truck.
	Mail.	Baggage.	Mail or Baggage.
Fixed charges, interest, insurance, taxes	15.0	18.75	1
Depreciation: trucks, batteries, tires and switchboard apparatus	18.82	23.53	1
Maintenance: labor and material	4.2	5.25	1
Operation: labor and power	.21	.26	1
Total charges	.33	.42	1
Saving of electric over hand truck	67%	58%	

In Fig. 10 one truck is shown hauling three other loaded trucks.

A very complete installation of 16 electric baggage trucks of the drop frame type has been installed at the North Station, Boston. These trucks are similar in size and general design, control, etc., to those described above, and are used practically entirely for handling express. In these trucks there is rather a novel braking feature. The operators' platform is divided into two halves, the left half operating the brake. Normally the brake is on, and to release it the operator has to press down the left half of the platform. This has the advantage of almost instant stoppage if the operator steps off his platform.

The conditions met with at this terminal are particularly severe. There are 738 trains handled daily, on 23 parallel tracks, with intermediate and side platforms from 7 to 16 feet wide. At the station end of the platforms the trucks have to ascend and descend a 12 per cent. grade, and as there are passenger gates at the lower end this requires very efficient and quick-acting brakes. So far these trucks have been successfully operated without accident. Another saving has been found to be in decreased damage. Packages frequently dropped off the hand trucks, but it has been found that breakages from this cause with the electric trucks are practically nil, owing to the electric drive, rubber tires, flexible frames, etc.

With an equipment of this size it is necessary to have a complete set of operating rules to prevent confusion. In the operation of the trucks all are carefully examined before being placed into service and each truck is numbered with figures three inches high for reference. The trucks are started step by step similarly to a street car. Operators are not allowed to converse with any one while in charge of a truck, and are cautioned to use great care at gateways and passages. When operating on the main platform at the bumper ends of the train tracks the trucks take the middle of the course except that in passing others those operating on the main platform are given the right of way over those approaching from trains. Running backward in the station proper is also prohibited, and no trailers are permitted. Trucks proceeding in the same direction must keep 15 feet apart.

The Canadian Pacific Railway have installed two of these electric baggage trucks at the Windsor Street Station, Montreal, Que., and having found them satisfactory, are ordering a number of others for different points on their system.

EFFICIENCY IN THE PUMPING STATION.

By Seabury G. Pollard.*

The following extracts taken from an article by Seabury G. Pollard, in Municipal Engineering, will doubtless be found of interest to many who are directly or indirectly responsible for the efficient management of pumping stations:—

Efficiency may be defined as the ratio of actual performance to predetermined standard performance. It is the elimination of unnecessary waste.

Let us consider an ordinary every day pumping station, such as those in most of our medium sized cities and in many of our larger ones. The buildings are not always practical. The engine room is fairly well equipped, the bright work and the brass bands shine attractively, the floor is fairly clean, not much escaping steam is apparent, there are no cracked steam cylinders, the flywheel is all there, a few records are kept and the engineer is apparently well satisfied with himself and the world in general. The boiler room is usually unattractive. It may be gloomy, dirty and repulsive. Possibly there is an unsightly junk pile in one corner, a dilapidated work bench in another or some broken engine parts under the window. The sanitary arrangements consist of a greasy wash pail and a grimy cupboard. Such conditions are reflected in the employees. The fireman in a listless manner now and then fills the furnace up with coal. He occasionally cleans the fires and takes out the ashes. Possibly more or less steam is escaping through a blownout joint, the heater may be stopped up, the damper will not work, the coal goes on the fire and "the smoke goes up the chimney" just the same and nobody from the manager down considers for a minute that there exist numerous preventable losses all along the line, which in the aggregate may amount to thousands of dollars annually.

Efficient Labor Required.—To avoid such losses it is necessary in the first place to employ only efficient and intelligent labor. In many municipal plants the executive is spared this trouble. The employees are selected for him, either arbitrarily because of their effectiveness in their respective wards and precincts, or through the medium of a civil service board. The first method is bad because the qualifications of the appointees are seldom taken into account. The second is often little better because the examining board is not acquainted with the character of work to be done and is therefore incompetent to judge of the fitness of the men. It does not eliminate political favoritism, and the best qualified men, having no difficulty in getting employment, pay no attention to the examinations. Pre-eminently the person best equipped to select the operating force is the engineering executive.

Operating Standards.—The next important problem before the waterworks operator is the fixing of operating standards. Duty trials of engines and efficiency tests of boilers are, or should be, made shortly after the installation of this equipment. If for any reason such efficiency trials have not been made, or if the results are not available, a competent engineer may be employed to study the conditions existing in the plant, to make such tests as may be necessary or desirable and to establish efficiency standards and proper methods of handling the plant.

* Consulting Engineer, Cincinnati, Ohio, Member of Illinois Water Supply Association.

THE SUPPLEMENTARY ESTIMATES FOR THE CURRENT FISCAL YEAR.

Supplementary estimates for the current fiscal year totalling $23,470,316 were tabled in the Commons, Ottawa, on May 20th, by Finance Minister White.

The most important item in the supplementaries is an amount of $4,000,000 to provide for the construction, leasing or purchase of terminal elevators, as foreshadowed during the discussion of the amendments to the grain act in the Commons.

There is an amount of $1,500,000 for improvement to highways, distributed among the Provinces according to population. The same fate may meet this appropriation, however, as met a similar appropriation last year if the Government again fails to accept the Senate amendments to the highways improvement bill.

For harbors and rivers there is a total vote on capital account of $3,300,000, including half a million each for new Government drydocks at Esquimalt and Halifax naval bases; $200,000 additional for Port Arthur and Fort William harbors; $600,000 additional for Victoria, B.C., harbor, and half a million additional for each of the harbors of St. John, Vancouver and Toronto.

For harbors and rivers in Ontario the important items include the following:—

Armitage Landing, wharf, $8,700; Bowmanville, repairs to piers, $12,000; Bracebridge, wharf, extension and warehouse, $9,600; Burlington Channel, renewal of west part of south pier, $20,000; Burlington, revetment wall, $8,000.

Cobourg, repairs to east pier, $5,500; Cobourg, reconstruction of centre pier, $15,000; Fighting Island (Detroit River), improvement of channel, $57,000; Fitzroy Harbor, wharf, $5,500.

Gananoque wharf, $18,000; Goderich, harbor improvements, further amount required, $8,000; Kagawong, wharf, $5,600; Kenora, wharf, $10,000; Kensington, wharf, $6,000; Kincardine, breakwater, $25,000.

Little Castor River, improvements, $10,000; Meaford, extension and repairs to revetment wall, $33,000; Nation River, improvements, $10,000; Newcastle, repairs to eastern pier, $15,800.

Peterboro', drydock, $25,000; Port Dover, harbor improvements, $50,000.

Port Hope, harbor improvements, $30,000; Rainy River, survey and maintenance of gauges, $16,000; Richard's Landing, wharf and warehouse, $15,000; River St. Lawrence, improvements of Canadian channel between Kingston and Brockville, further amount required, $10,000; Sault Ste. Marie, wharf improvements, $34,500; Severn River at Washago, construction of dams and removal of rocks, $10,000.

Toronto, to pay over two accounts to R. Weddell & Company in connection with new entrance channel to harbor, $22,960; Vail's Point, wharf, $8,500; Victoria Harbor, wharf, $16,000; Wellington, wharf and harbor improvements, $20,000; Whitby, harbor improvements, further amount required, $20,000. Under the item of canals there is an amount of $250,000 additional for construction on the Trent Canal. It is understood that this is to begin the work of completing the northern outlet of the canal from Lake Simcoe. A contract amounting to $1,000,000 is to be let at once.

In addition to the expenditures provided for in the main and supplementary estimates it is to be noted that the Government has yet to bring down the railway subsidies, which will run up, it is expected, well into the millions. There is further expected legislation granting the Canadian Northern Railway, by way of subsidy and loan, of an amount something like $25,000,000.

The Intercolonial Railway calls for an additional expenditure of $756,000 on capital account.

The main items for new public buildings include: $100,000 for a new customs house at Halifax, $70,000 for a new post-office at St. John, $350,000 for a customs house examining warehouse at Montreal, $50,000 for a new public building at Brantford, $150,000 for enlargement of Hamilton post-office, $60,000 for a public building at Sudbury, $300,000 for barracks and drill hall at Winnipeg, $200,000 for Vancouver drill hall, and $100,000 for customs house at Edmonton. The expenditure for public buildings in the province of Ontario amounts to $1,277,655.

The expectation that the Government's supplementary programme for expenditures for this year would be on a lavish scale has been justified. The main estimate calls for an expenditure of $179,152,183, which, added to the supplementaries, makes the total authorized expenditure for the current year $202,622,500. This is an increase of $33,000,000 as compared with the estimates passed by the Government last session.

SIMPLE METHOD OF OBTAINING CORRECT MEAN LINE AND AZIMUTH.

By J. A. Macdonald.*

Necessity is the mother of invention, they say. The writer, being located at the present time (May) in Prince Edward Island, and being far from a town or railway station, and not being provided with the necessary paraphernalia to take direct astronomical observations, resorted to a very simple method, which not only gave at the moment correct meantime, but also azimuth, and both probably more accurate than by the usual methods of hour-angle of Polaris with a transit-theodolite. By the method hereunto described no instrument at all is required; no nautical almanac nor mathematical tables nor formula. There is, however, only one moment in the 24 hours when the trick can be done, and if the sky is hazy it may not be done at all. It requires a fairly clear sky, so that Polaris and another star may be seen in precise range.

The constellation in the northern heavens known as the Great Bear, the Plow, the Dipper or Charles' Wren, is doubtless familiar to all. Two of its five bright stars are known as the "pointers" from their pointing to the North Star or Polaris. The middle star in the tail or handle, as shown in the diagram, is the star which comes to the meridian at the same time as the North Star.

Another bright star comes to the meridian when Polaris is in the same vertical plane with the star Delta (δ) in the constellation Cassiopeia. When both stars are on the same vertical range with a plumb line it is very near the meridian.

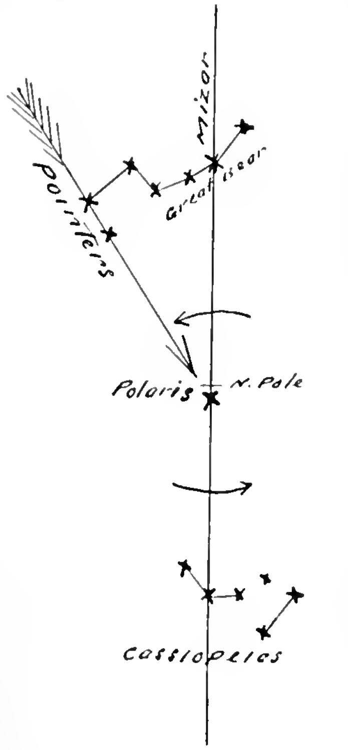
This method is practicable only when the star Delta is below the pole during the night. When it passes the meridian above the pole, it is too near the zenith to be of service, in which case the star Mizar, the last star but one in the tail of the Great Bear, may be used instead.

Delta, Cassiopeia is on the meridian below Polaris and the Pole at midnight on April 10th, and is, therefore, the proper star to use at that date and some two or three months before and after. Six months later the star, Mizer, (Zeta Urs. Maj.) in the tail of the Great Bear, will supply its place, and will be used precisely in the same manner. The method given in this article can not be used with advantage at places below 38° north latitude, neither can it, on account

* Hermanville, P.E.I.

of the haziness of the atmosphere near the horizon, on every night, for it requires a fairly clear atmosphere.

The diagram, drawn to scale, exhibits the principal stars of the constellations of Cassiopeia and Great Bear, with Delta (δ) Cassiopeia, Zeta (ζ) Ursae Majoris (also called Mizar), and Polaris on the meridian, represented by the straight line; Polaris being at lower culmination. This method is given in Lalande's Astronomy and was practised on the Ohio and Pennsylvania boundary with great precision.



Held perpendicular to the line of sight directed to the pole, with the right-hand side of the page uppermost, will represent the configuration of the constellations with Polaris near eastern elongation at midnight about July 10; inverted (in natural position) it will show Mizar of the Great Bear and Polaris on the meridian (the former below and the latter above the Pole) at midnight about October 10; and held with the left-hand side uppermost the diagram will indicate relative situations for midnight about January 10, with Polaris near western elongation. Turned upside down it will show Delta Cassiopeia and Polaris in the meridian at midnight about April 10. The arrows indicate the direction of apparent motion, while the large arrow through the "pointers" indicates position of Polaris at any time.

Finding Correct Mean Time.—Table I.—Begin to watch plumb line for "A" to appear vertically below Polaris:

About—		On line
July 20	5 a.m.	5.30 a.m.
August 20	3 a.m.	3.28 a.m.
September 20 ...	1 a.m.	1.26 a.m.
October 20	11 p.m.	11.24 p.m.
November 20 ...	9 p.m.	9.22 p.m.
December 20 ...	7 p.m.	7.24 p.m.

Table II.—Begin to watch plumb line for "B" to appear vertically below Polaris:

About—		On line
January 20	5 a.m.	5.22 a.m.
February 20	3 a.m.	3.20 a.m.
March 20	1 a.m.	1.30 a.m.
April 20	11 p.m.	11.24 p.m.
May 20	9 p.m.	9.26 p.m.
June 20	7 p.m.	7.24 p.m.

When a plumb line matches "A" or "B" the Pole Star is approaching the meridian and the true local mean time then is the time in column "on line." Interpolate for intermediate days, subtracting four minutes for each day after or adding four minutes for each day before any given date.

Example.—July 25, begin to watch plumb line about 4.40 a.m., and Polaris will be exactly on line at 5.10 a.m. correct mean local time. The interval from July 20 to 25, 4 days multiplied by 4 is 20. This sum subtracted from 5.30, time on line July 20, is 5.10. To change this into local standard time add 4 minutes for each degree west of the time meridian and subtract same for stations east of the meridian. Thus at the point where I write, being 2°15′ west of the 60th standard meridian, 9 minutes must be added to the observed time for standard time. At Toronto add 17 minutes; at Ottawa add 3 minutes; at Winnipeg add 29 minutes; at Calgary add 35 minutes; at Vancouver add 15 minutes, and at Montreal subtract 6 minutes from the standard meridian times at those several places.

To Obtain Azimuth.—Azimuth, or the direction of the meridian can also be obtained directly at the same time and in the same manner.

When the Polaris and Mizar are in line with the observer this line is approximately on the meridian, but a little east of the true line. The North Star is exactly in the meridian 7.15 minutes after it has been in the same vertical plane with Mizar, and may be sighted to after that interval of time with perfect accuracy for 1913. The interval between the time when Mizar and Polaris are on the same vertical circle and the time when Polaris is on the vertical circle through the North Pole is increasing 0.33 minute a year, so that, in 1914 the interval will be 7.5 minutes.

The interval between the time when Delta Cassiopeia and Polaris are on the same vertical angle and the time when Polaris is on the vertical circle through the North Pole is 7.69 minutes for 1913 and is increasing 0.33 minute per year, so that in 1914 the interval will be 8.02 minutes.

A light placed back of the head will aid in seeing the plumb lines which may be hung in a convenient window and let the bob hang in a dish of water to prevent the wind from disturbing the line, or the observation may be made with closed window.

In marking out the meridian, use two plumb lines and connect them by a row of tacks, if the work is done indoors, driven in the porch floor in the range of a pillar, post or window casing.

VISIT OF A PRODUCTION ENGINEER.

Mr. Willis Bell Richards, of the firm of Gunn, Richards and Company, New York City, was a visitor at *The Canadian Engineer* office last week. Mr. Richards is well known in Canada as a production engineer, having been of valuable service upon many occasions to various departments of the Dominion government, as well as to many private corporations throughout the country.

The firm recently opened new offices in the Eastern Townships Building, Montreal, with Mr. H. Victor Brayley as manager for Canada. Mr. Brayley was formerly secretary of the Ottawa Branch of the Canadian Society of Civil Engineers, and held a government engineering position. Mr. James Newton Gunn, the president of the company, is one of the best known production engineers in the United States. He has been connected for many years as lecturer with New York University and the Massachusetts Institute of Technology. The firm employs over fifty trained engineers and also a number of expert accountants, who work in co-operation with the engineers in organizing the shops, offices, buying departments, etc., of industries of all types, in making appraisals and in scientifically analyzing production costs and power costs.

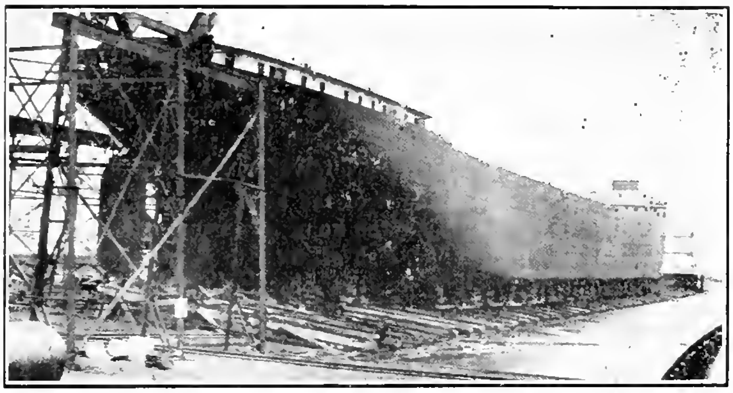
Mr. Richards was called to Canada by one of the leading Canadian capitalists to advise in regard to improving the organization, decreasing the running expenses and increasing the sales of two of the largest manufacturing concerns in the Dominion.

S.S. "JAMES CARRUTHERS."

The launching of the steamship "James Carruthers," which took place a couple of weeks ago at the yards of the Collingwood Shipbuilding Company, marked an epoch in the shipbuilding industry in Canada, in that the vessel is the largest bulk freighter ever built in the British Empire. Some idea of the magnitude of this vessel will be gathered from the photograph accompanying this article, and we are pleased to be able to give to our readers some information regarding the engineering features of this vessel.

The dimensions of the ship are as follows:—Length over all, 550 feet 3 inchs; length on keel, 529 feet; beam moulded, 58 feet; depth moulded, 31 feet, with a carrying capacity of over 10,000 gross tons on 19 feet draft.

The arches and web frames are spaced 12 ft. centres, forming transverse girders, with channel bottom and side frames between, spaced 3 feet centres, plate floors in double bottom on alternate frames. The vessel is constructed witb a complete double bottom, 5 feet deep and side tanks of same width, to height of main deck stringer, for water ballast, and forming a double skin over this portion of the ship to a point above the deep load line, the capacity of these tanks, including the peak tanks, engine-room tanks and deep tank forward being approximately 4,600 tons.



S.S. "James Carruthers" Just Before Launching.

The auxiliaries for handling and manoeuvring the ship are as follows: Steering gear—a 9-ft. by 9-in. quadrant geared steering engine, built by the American Engineering Company of Philadelphia, placed aft on main deck, direct connected by toothed quadrant to rudder stock and controlled from steering stands in the pilot house and on top of same by a hydraulic tele-motor. In addition to this there is an Aker's emergency steering gear, a complete and independent steam gear, placed also on main deck, on port side, direct connected to a toothed quadrant on rudder stock and controlled from steering stand on top of pilot house by jacks and pipe transmission. Steam is always turned on this gear. If any accident occurs to the regular gear, the Aker's gear may be thrown in, in three seconds, by means of a crank on steering stand controlled by the officer on the bridge which, at the same time, trips the regular gear, and throws it out of service for the time being, this gear being a valuable acquisition, where, in the event of a breakdown of the regular gear, in the rivers, without such a device collision or stranding is almost inevitable. Windlass—This is of the Emerson-Walker, quick-warping direct grip type, arranged to handle two four-ton Britannic stockless Bower anchors and 2¾-inch cables, this being the largest windlass of the type ever installed in a lake vessel. The anchors are arranged to stow in pockets entirely within the hull. The balance of deck machinery consists of four 8-inch by 10-inch single drum mooring winches, fore and aft on spar deck; one 8-inch by 10-inch single drum winch in windlass room, and one 8-inch by 10-inch double drum winch on spar deck aft, arranged to handle 3½-inch circumference wire mooring cables, manilla lines being dispensed with for this purpose. The second drum on the after winch is to take the kedge anchor warp, a 4½-inch circumference wire cable, and by means of which the stern anchor, weighing 4,000 lbs., and placed on an inclined platform, may be instantly let go over the stern of the vessel, in case of accident in the rivers, when the stern of the vessel would otherwise in the current swing on to the bank, involving serious risk of damage by collision with other vessels. Two 5-inch by 5-inch single drum hatch winches are located amidships to handle the hatch covers, which are of steel, and are opened and closed by a small steel cable led to these winches. All deck winches were supplied by the Chase Machine Company, of Cleveland.

The navigating outfit is very complete and thoroughly up-to-date in every particular. It comprises repeating telegraph to engine room, with stands inside pilot house and on top, mates' telegraph for docking purposes with stands in pilot house and aft on the spar deck, all with large dials, having additional emergency signals; engine whistle pull inside and on top of pilot house and on each bridge; two sets of main signal whistle pulls, one for emergency use, with levers inside and on top of pilot house; a fog bell, a steering compass in pilot house and standard compass in binnacle on top of house, of Dobbie McInnes make, a helm tell-tale, with indicator on top of pilot house, and direct connected to rudder stock, showing true helm angle at all times, in case of derangement of the telemotor apparatus. There is also installed on top of pilot house, a McNab engine dejection indicator, with direct connection to main engines, showing, by sight in daylight and by sound at night, every movement of the engines ahead or astern. This instrument is a splendid safeguard against the very costly accidents which occur frequently through a mistake in signals between the bridge and engine room. A Morrison trim gauge forms part of the equipment, and a draft gauge, by which the mates can read the exact draft of the ship in rough weather or at night, from an indicator and scale located on forecastle bulkhead forward and on deckhouse aft. A Thomson sounding machine is installed on the spar deck abaft the forecastle bulkhead, with a crane on the bulkhead to handle the sounding device when overboard.

Awnings are fitted over forecastle deck and pilot house, and the usual weather and dust cloths, etc.

There is a complete electrical installation, consisting of two 10-kw. generators with capacity for about 200 lights, being ample accommodation for hold and decks lights and running lights, arranged on separate circuits, and an electric tell-tale in pilot house to give indication of any arrangement of the running lights.

The propelling machinery consists of triple expansion engines with cylinders 24, 40 and 66 inches by 42-inch stroke, supplied with steam by three Scotch marine boilers 15 feet diameter and 11 feet long, 185 lbs. steam pressure and equipped with Howden system of forced draft, developing 2,400 indicated horse-power and designed to give the vessel a speed of 11 miles per hour, loaded, and 13 miles light.

The engines are located directly on the tank top, as far aft as possible, as usual in these vessels, with the boiler forward of this, located athwartships, three abreast on very

heavy saddles and a cross coal bunker forward of fire hold, with capacity for about three hundred tons, and fuel hatch fitted in tank, above spar deck.

The engines are handled from a working platform, below main deck level, of convenient height to suit the levers, with dynamo room abaft this. Great care has been taken in laying out the engine room to ensure ample working space and at the same time studying the comfort of the engineers' crew.

The pumping equipment comprises one centrifugal and two duplex pumps located in the lower engine room to take care of water ballast, sanitary pump and deck pump, one duplex main feed, one duplex auxiliary feed and fire pump on upper engine room floor and air, bilge and cooler pumps direct connected to engine, also hand bilge and fire pumps forward and aft.

A refrigerating machine having capacity of three tons in 24 hours, by Kroeschell Bros., Chicago, is located in the upper engine room, and piped to refrigerator in the deckhouse above, this being fitted with cooling coils and also an ice door, opening on spar deck, for use should a supply of natural ice at any time be required.

TRAFFIC THROUGH THE SAULT STE. MARIE CANAL.

The annual statistical report on lake commerce passing through the canals at Sault Ste. Marie, Mich., and Ontario during the season of 1912 has been issued by Lieut.-Col. Mason M. Patrick, of the U.S. Army Corps of Engineers. The total freight traffic through both the American and Canadian canals, of 72,472,676 short tons for the season of 1912, shows an increase of 36 per cent. over the previous year. All items of freight show an increase except coal, salt, copper and building stone. The season of navigation continued for a period of 7 months and 26 days. The traffic through the American canal was 45 per cent. of the total freight and 55 per cent. of the total net registered tonnage, while the traffic through the Canadian canal was 55 per cent. of the total freight and 45 per cent. of the registered tonnage.

Of the total traffic 55,377,687 short tons was eastbound, and 17,094,989 was westbound. The transportation charges, including loading and unloading, on freight passing through both canals were $40,578,225.40.

The total expenditures for operating and repairs on the American canal for the year 1912 are given in the report as follows: Operating, $71,135.66; repairs, $81,061.68; total, $152,197.34. The cost per freight ton was 4.64 mills.

MEDICINE HAT'S STREET RAILWAY.

Medicine Hat ratepayers have sanctioned a by-law giving an exclusive franchise to the Montreal Engineering Company to operate an electric street railway in the city. The franchise is for a period of 25 years. Work is to commence immediately on the construction of the plant.

The Montreal Engineering Company, which has secured the franchise represents Sir Max Aitken and his associates and is the company which built the Porto Rico railways, the Demerara Electric, the Camaguey Company and the Trinidad Electric. It numbers among its directors Messrs. R. O. Sweezey, A. R. Doble, F. P. Jones, Fred C. Clarke and Victor Drury.

PRESERVING FENCE POSTS FROM DECAY.

Wood-rot, in all its forms, is due to the action of fungi working under suitable air and moisture conditions. In fence posts these conditions are most favorable at or near the surface of the ground and hence it is there that decay first starts. Some woods, like the cedar and tamarack, are more resistant to fungus attack and may last, as fence posts, from eight to ten years. Unfortunately, however, the supply of these woods has grown very scarce, and one is faced with the alternative of importing durable material at a high price or of applying preservatives to the common non-durable woods which grow in his own wood lot. As the latter alternative is not only cheaper, but also much more effective, it is of considerable economic interest to know how these wood- preservatives are applied.

Creosote, a "dead" oil of coal tar, is perhaps the best preservative for this purpose, as it does not dissolve out of the treated wood, when in contact with moist earth. It costs from eight to fifteen cents per gallon.

There are two methods of applying the creosote, but before either method can be applied it is necessary to have the posts well seasoned if the best results are desired. This seasoning is best accomplished by peeling the bark from the posts and then stacking them in loose piles in the open air for several months, so the amount of water in the wood may be reduced to the smallest per cent. possible.

The brush method consists in applying the creosote like a coat of paint to the lower portion of the post, up to a point six inches above the ground line, the creosote being first heated to one hundred and eighty degrees Fahrenheit. Two or more coats may be applied, time being allowed between each application for the creosote to soak into the wood.

What is known as the open tank method, while more expensive, secures deeper penetration and gives better results, especially when the posts are split or checked. The creosote is heated to boiling point in a metal tank and if such is not available, a simple and effective apparatus can be made by boring two holes, about two feet apart, in the lower half of one of the staves of a watertight barrel and screwing into these holes two pieces of iron piping three to four feet long which are connected by a shorter vertical pipe with two elbow-joints, thus forming a complete circuit somewhat resembling the handle of a mug.

The barrell is then filled with enough creosote to cover both upper and lower pipe holes and a fire is kindled under the lower horizontal pipe which heats the creosote in the pipes and creates a circulation which continues until all the creosote within the barrel is at boiling point. The posts are then placed in this boiling liquid for about five hours, after which they are immediately transferred to another barrel of creosote, or else the fire is put out and they are allowed to remain in the tank until the creosote becomes thoroughly cooled.

In this process the preliminary heating drives some of the contained air out of each wood-pore, and when the posts are allowed to cool in the creosote, a partial vacuum is then created in each pore which draws the creosote into every fibre. Poplar posts, which ordinarily last but three to four years, after the above treatment will last twenty years, and the same applies to all other tree species in Canada. All that is essential is thorough seasoning before treatment. Further information on this subject can be obtained on application to the Forestry Branch, Ottawa.

RAILROAD TIMBER-TREATING PLANT.

By F. J. Angier.*

The Baltimore and Ohio Railroad has put into operation a new timber-treating plant, which has just been completed at Green Spring, W. Va. The new plant is one of the most complete and modern timber-treating plants in America. It covers sixty acres, and is situated close to large areas of timberland along the South Branch Valley of the Potomac River. The requirements of the Baltimore and Ohio system approximate 2,500,000 ties annually for renewals, and with the new plant in operation a large proportion of these ties will be treated by the company. Other timber for railroad use will also be treated at the plant.

The timber-treating plant is equipped with two treating cylinders, or retorts, as they are commonly called. These retorts are seven feet in diameter and 132 feet long, made of ¾-inch steel, and built for a working pressure of 175 pounds to the square inch. Each of the retorts rests on nine concrete piers, and is securely anchored to a centre pier with six 1¼-inch bolts. On the remaining eight piers the retort rests on cast-steel saddles, and placed between the saddles and an iron plate embedded in the concrete are nests of steel rollers, each nest being made of three rollers two inches in diameter and ten inches long.

At each end of the retort is a door which swings on steel rollers, and can be opened and closed easily by one man, notwithstanding the weight of 6,400 pounds each. The door consists of a steel frame with flanged steel dished head one inch thick. The retorts are equipped with heating coils, and also with perforated pipes. The pipes are used to obtain a more perfect distribution of steam when green timber is being artificially seasoned, as well as for the circulating device used in the card process.

The main building of the plant is of steel frame construction, with corrugated iron sides and concrete roof. The floors of the building are of cement, and a concrete basement so constructed that should any of the preservative be spilled it can be recovered. In the basement is a concrete sump equipped with an electric device which indicates to the engineer in charge that the sump is filled. The sump is emptied by means of an ejector, the liquid passing into a settling tank about 50 feet from the building. The settling tank is also of concrete construction, with dimensions of 20 feet in width, 50 feet in length, and approximately 10 feet in depth. The tank has four compartments, and after the drainings from the plant enter the first compartment the liquid is forced to travel through each of the other compartments in a circuitous path to the last compartment. By this time any creosote carried from the plant falls to the bottom, because of its greater specific gravity, and enters a well in the bottom of the last compartment of the settling tank. Here a bilge pump, operated by electricity, picks it up and carries it to an underground tank, and then by compressed air it is carried into the working tanks.

The boiler-room is situated adjacent to the main building, the dimensions of the room being 30 feet by 40 feet. The boiler-room contains two horizontal return tubular boilers of 150 horse-power each, built for 125 pounds working pressure per square inch. Space is provided in the room for a third boiler to be installed when the requirements of the railroad justify the enlargement of the plant. A boiler-feed heater, injector and feet water pump complete the equipment in the boiler-room.

The oil storage tank is 40 feet in diameter by 30 feet high, having a total capacity of 280,000 gallons. There is also a storage tank for a concentrated solution of zinc-chloride, the dimensions of which are 15 feet in diameter by 20 feet high, with a capacity of 25,000 gallons. The oil storage tank is equipped with a system of heating coils made in four sections, the combined heating surface of which is 500 square feet. An angle stem thermometer is placed in the side of this tank to enable the oil being kept at a constant temperature of about 120 degrees Fahrenheit.

Near the storage tank is an underground unloading tank, 6 feet in diameter by 60 feet long. The tank is enclosed in a concrete pit, which will prevent waste of the creosote in the event that leakage occurs. The tank will withstand an air pressure of 50 pounds per square inch, and creosote is forced from this tank into the storage, or working, tanks by air also. The working tanks and pressure tanks are all located inside the building, so that they can be kept warm and the temperature of the working solution retained at 190 degrees. The locating of these tanks inside the building also accomplished a further economy in the consumption of fuel, particularly in cold weather.

The working tanks are 24 feet in diameter by 20 feet high, each having a capacity of about 68,000 gallons. They rest on concrete foundations six feet above the floor line, being equipped with cast-iron radiators for heating the solution. Each tank has three sets of radiators, working independently of one another. The combined heating surface of the radiators is 441 square feet. Each tank is also equipped with air coils for agitating a mixed solution of creosote and zinc chloride. Air is admitted at 100 pounds pressure, and distributed in such manner as to completely mix the solution in from two to five minutes. The tanks are also equipped with mercury gauges, which show the true reading in tub feet and gallons, regardless of the temperature. This avoids the necessity of making correction for temperature readings with these gauges. Besides the mercury gauges, each tank has a syphon regulator, which regulates the steam supply to the radiators and automatically opens and closes the steam supply valve in maintaining the required temperature.

The pressure tanks are 8 feet in diameter and 14 feet high, made of ⅞-inch steel for a working pressure of 175 pounds. They are in reality a combination of pressure, measuring and drain tanks, and are located in such a way that they are readily filled while the treating cylinders are being filled preparatory to treating a charge of timber. Compressed air is then applied through the top of these pressure tanks, and the preservative is forced through a pipe in the bottom connected with the cylinders. Pressure is maintained until the required absorption is obtained in the timber, after which the valve is closed, and any preservative remaining in the tank can be returned to the working tank by means of the compressed air already in the pressure tank. There is also a sufficient amount of compressed air in this tank to force all of the solution in the treating cylinder back to the working tank. The tanks are also used for measuring purposes, being equipped with mercury indicators, which show the amount of solution, and thus informing the engineer as to the amount of solution going into the timber he is treating. They are also used as drain tanks to catch and measure the solution taken from the timber during the vacuum and draining process. The bottoms of the pressure tanks are only slightly lower than the treating cylinders; and, though all of the drainings from the charge would not flow into the pressure tank by gravity, this is easily and quickly accomplished by admitting atmospheric pressure to the treating cylinder while the pressure tank till maintains a vacuum. This combination of pressure-measuring-drain tank is entirely unique with the plant at Green Spring. It was worked out by the writer, assisted by Card and McArdle, who were the draftsmen in getting out the pipe plans. It eliminated entirely the dirty and ex-

* Superintendent of Timber Preservation, Baltimore and Ohio Railroad System.

pensive pressure pumps commonly in use in timber-treating plants

Recording gauges and recording thermometers are connected to the treating cylinders. This places the superintendent in complete touch with the treatment in all of its details, the charts indicating the temperature, pressure and vacuum recorded for every moment the plant is in operation.

The plant is heated throughout by steam, the vacuum system being used, all condensation being returned to the boiler-feed heater and thence to the boilers. A 50-kilowatt generator furnishes the light for the plant and the yard, there being three arc lamps and about 50 incandescent lamps in the system. The electric plant also furnishes current to operate two 10 horse-power centrifugal pumps and a single horse-power bilge pump. The centrifugal pumps are 8-inch ones, used to circulate the mixture of creosote and zinc-chloride in the retorts while using the Card process. The latter is in the settling tank and is used to pump creosote, that may have settled out from the drainings, into the underground unloading tank.

An experimental plant is situated adjacent to the main building. This plant consists of a complete physical and chemical laboratory. The experimental cylinder is 30 inches in diameter and 9½ feet long, or large enough to hold three or four ties. There are two working or pressure tanks, underground drain tank, pressure pumps and electric centrifugal pump. The tanks are equipped with the latest gauges and thermometers, and the entire plant is so designed that any process can be used, and pressure can be supplied as high as 300 pounds. The chemical laboratory adjoins the physical laboratory, and creosote distillations, zinc-chloride analyses, etc., will be made.

The office building is of concrete, and is fireproof in its entire construction. The same is true of the other buildings in the plant. The hose and engine-houses are of wood, but these are small and located some distance from the other buildings. A fire system has been installed as a protection against destruction in this way, and a fire department will be organized from among the employees, the organization of which will be similar to that at the large terminals, shops and other centres on the Baltimore and Ohio system. A 6-inch water main has been laid the entire length of the tie-yard, and every 300 feet there is a hydrant. The hose-house is near the office, and is equipped with a reel of 300 feet of hose. Water pressure for fire emergency is maintained by a high 50,000 gallon water tank, kept filled at all times.

At the present time the water used in the timber-treating plant is being pumped from the Potomac River, but this arrangement is but temporary until a permanent water system can be built for the joint use of the timber-treating plant and for supplying water to locomotives in train service. The permanent water plant plan calls for two pumps, located at the plant in a concrete well about 100 feet below the surface of the ground. The depression was deemed necessary on account of the lift from the river. Water will be pumped into the high storage tanks and fed by gravity throughout the plant and yard.

Practically all of the ties treated at the plant to date are oak, the number being approximately 200,000. The standard tie in use on the Baltimore and Ohio is 7 inches by 8 inches and 8½ feet long, containing 3⅓ cubic feet. These ties are unloaded and cribbed in piles of seven and one, and are handled by piece-work. It is the intention to air-season all ties. However, if they are not received in quantities sufficient to properly air-season, the plant is designed to take care of this by giving a preliminary steaming and vacuum before the injection of preservatives.

All storage yard tracks have three rails, the outside pair being of standard gauge and the inside rail fixing a 30-inch gauge for the tram cars. In loading for treatment the ties are classified as hard and soft woods and as No. 1 and No. 2. For this work the men are paid at a rate per tram instead of per tie, as is the case of unloading and cribbing for seasoning. Thus it makes no difference whether there are 30 or 40 ties on a tram; the cubical contents are practically the same, and the amount paid is the same. There are 130 tie-cars used to deliver the ties to and from the treating cylinders.

The location of the timber-treating plant is believed to be admirably suited for all purposes, being in near proximity to large timber areas. Green Spring is at the junction of the Romney branch with the main line of the Baltimore and Ohio system. The Romney branch, which extends 16 miles to Romney, W. Va., and the Hampshire Southern Railroad, extending 38 miles farther to Petersburg, tap a timber tract of several thousand acres, much of it being virgin timber. The outlet for all timber adjacent to the lines mentioned is by way of Green Spring, and in marking the timber it is in reality merely a question of stopping the timber at the plant to have it seasoned and treated.

THE R. M. S. "KYLE."

The R.M.S. "Kyle," which has been built and engined at the Neptune Works of Swan, Hunter and Wigham Richardson, Limited, to the order of the Reid Newfoundland Company, of St. John's, Newfoundland, went for a very successful trial trip on Monday, the 5th inst.

The steamer is a finely modelled screw vessel of 220 ft. in length by 32 ft. beam, exceptionally strongly constructed for running through ice which she will often meet on her mail and passenger service on the Newfoundland and Labrador coast.

The passenger accommodation is amidships for the first-class passengers. These are 68 in number, and have a large smoking room on the promenade deck, a dining saloon and music room on the upper deck, and state rooms, including a ladies' room on the main deck.

The second-class passengers are placed aft in two compartments on the main deck, one for men accommodating 102, and the other for women, with sleeping accommodation for 39.

The captain's house is on the promenade deck, the other officers and engineers are in rooms at the sides of the engine casing, and the seamen, firemen, and stewards are forward.

The steamer is provided with a complete installation of electric light, including a search light, an efficient arrangement of steam heating suitable for the climate, and wireless telegraphy.

The propelling machinery consists of a set of single screw triple expansion engines, supplied by steam from two large boilers working under Howden's forced draught, the whole having been constructed at the Neptune Works. On the trial trip they worked without the slightest hitch, giving satisfaction to all concerned, and driving the vessel at a speed of 13¾ knots per hour.

The owners were represented by Mr. R. G. Reid, one of their managing directors, and the builders by Mr. G. F. Tweedy, one of the managing directors of Swan, Hunter and Wigham Richardson, Limited.

DESIGN OF STRUCTURAL STEEL PLANT.

E. H. Darling, C.E., A. M. Can. Soc. C.E.*

General Conditions Controlling Design of a Plant of 10,000 Tons a Year Capacity.—A plant for the fabrication of structural steel for the Canadian market must be equipped for a wide range of work, for, while higher efficiency can usually be attained by specializing on one class, it is not always possible to do so for the following reasons:—

(1) Contracts of a uniform nature cannot always be obtained; and,

(2) Almost any contract has more or less variety of work involved in it.

Certain classes of work, such as building and highway bridge work, are required during the summer months only, while railway work can be done all the year round. By properly combining the two classes there will be less chance of slack seasons for the shop.

Location.—The location of a structural steel plant is subject to the same general principles that influence other manufacturing enterprises, and, while there may be many secondary conditions that will have more or less weight, the four main ones are: (1) The market; (2) the supply of the right class of labor; (3) access to raw material; and (4) the supply of power.

1. **Market.**—The market for structural steel depends on the class of work sought. Railway work is so widely distributed that good railway connections are of more importance, within reasonable limits, than location. Freight rates do not necessarily enter into the question, as the railways haul all such material and erection equipment, which is for use of their own roads, free of charge. For this reason, as well as others, connection with several railways is desirable. For mill building work, the greatest demand will be in industrial centres, although much of the same class is used in large public buildings, such as armories, churches, auditoriums, rinks, etc. For beam and general building

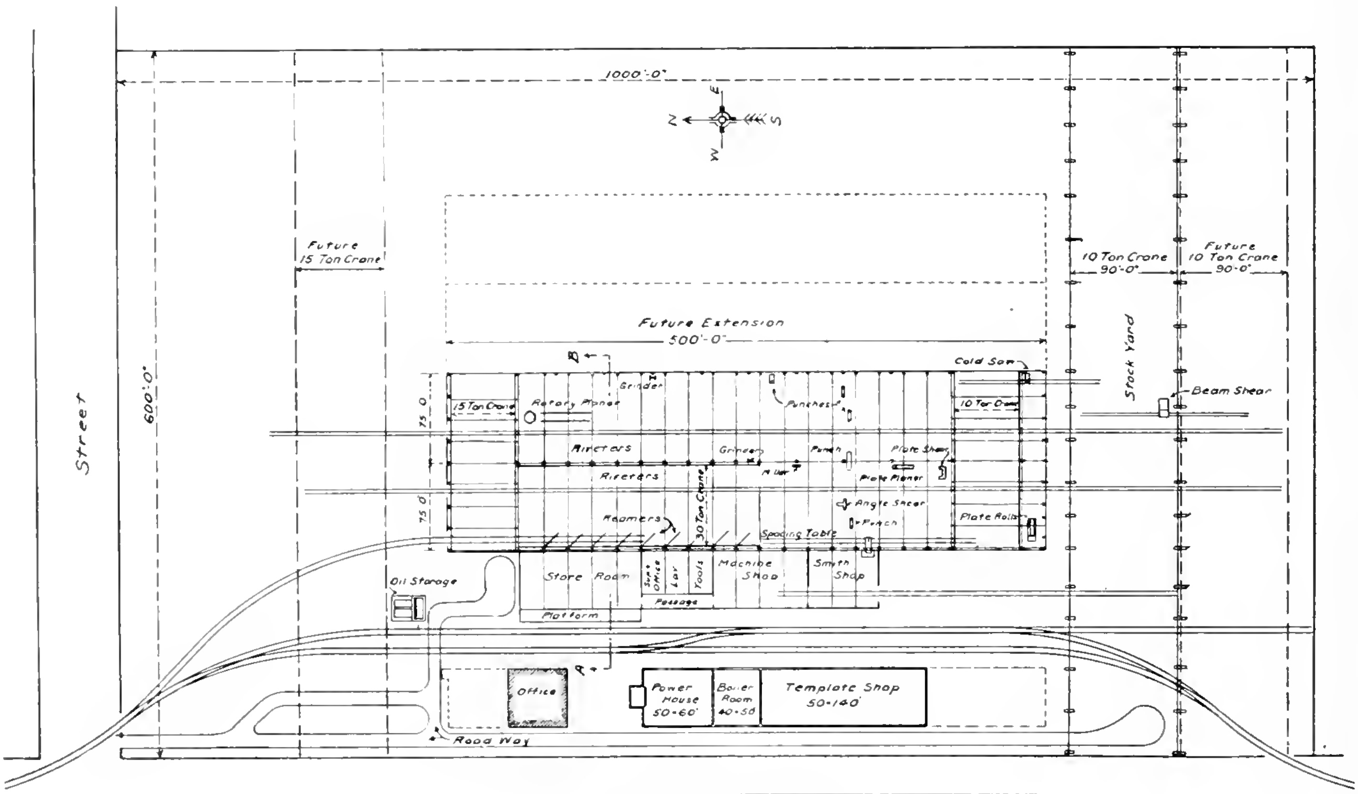


Fig. 1.—Showing Ideal Layout.

But apart from this, as the plant is a new one, whose market is not assured, it should be laid out with the idea of doing general work, and then, as the company finds its place in the business of the country, it may develop those lines which prove to be most profitable.

To secure this desirable flexibility of capacity in a plant having an output of 10,000 tons a year, it will be found advisable to have two main departments: first, a structural shop for all kinds of light truss and beam work, with facilities for handling pieces of five to ten-ton weight. Second, a girder shop where fifty-ton girders can be handled economically. A plant constructed on these lines, with all the necessary subsidiary departments, will be able to turn out any type of railway bridge up to 300 feet in span, and at the same time can be operated efficiently on any ordinary light work.

work, such as building contractors require, large commercial and business centres are the best markets. As most of such material has to be transported by team to the building site, good roads are necessary to handle this business. Steel highway bridges are required to replace old spans in the well-settled rural districts, or for new bridges in rapidly growing sections.

In finding the "centre of gravity" of a market, i.e., the point from which it will be possible to serve the largest number of customers, freight rates and cost of transportation should be considered rather than distances. For various causes, due to questions of competition and peculiar conditions existing in Canada, it will often be found that it costs more to make a shipment to a nearby place than to one at a greater distance. From a shipper's point of view, therefore, the latter place is nearer than the former.

The value of a market, however, depends largely upon the amount of competition that will have to be met; so in finding the centre of gravity it will be necessary to assign

* McPhie, Kelly & Darling, architects and engineers, Hamilton, Ont.

"weights" to various cities or districts according to how well they are served by existing companies.

2. **Labor.**—The cost of labor in the manufacture of structural steel is such a large percentage of the total cost that the question of obtaining a sufficient supply of the right kind deserves careful consideration. It will be necessary, in the first place, to secure experienced foremen and leaders, and these can only be obtained from other plants. With these as a nucleus it will be possible to train up intelligent laborers to do a great deal of the work, but, owing to the changes that are constantly taking place in a large organization, there will always be a need for men who have had some experience in a structural shop. Such workmen can more readily be obtained at some point near or in easy reach of other structural plants, while at other points it will be necessary to have a well-organized employment department to look after this. As many as two hundred men will be required to operate the plant, who, with their families, may mean that one thousand persons will be supported by it.

Raw Material.—Apart from a small amount of machine shop supplies, such as any manufacturing concern uses, "raw material" means only one thing in the structural steel business, and that is the rolled steel plates, beams, angles, etc., used in fabricating. There were over 600,000 tons of steel imported into Canada last year and by far the larger part of this quantity was in the form of structural material. Most of this comes from the United States, with Pittsburg as a centre. European manufacturers are at a great disadvantage in competing for this trade, because ocean transportation means more handling and serious limitations to the size and length that can be shipped.

It is of great convenience to a structural steel company to be as near as possible to its source of supply. Not only will it mean a big saving in freight rates at times, but what is often of more importance, it will save delay in getting material, and when mistakes are made in shipments they are more easily remedied.

The further removed a plant is from its source of supply the more necessary it is that a stock of material be carried. This requires a lot of capital, but, as a rule, it will be found very profitable, as well as a great convenience.

Power.—Compared with many other lines of manufacture, a structural steel plant does not need as much power in proportion to its output, and in this case not more than two hundred and fifty horse-power will be required. The most convenient form for it, as will be shown below, will be in electrical energy, and it is usually easy to obtain it in manufacturing centres. But it may happen that an otherwise desirable location does not offer this advantage, and then a power plant will have to be installed. This will mean the investment of extra capital and an increase in operating expenses, which must be taken into consideration.

There are a great many secondary conditions that influence a choice of location, such as climate, special inducements from municipalities, personal preference, etc., which will all deserve careful consideration, but it must be remembered that a mistake made at this stage will handicap the industry for all time.

Choice of Site.—An ideal site for a structural steel plant is not readily obtainable. A large area is essential, even for a comparatively small plant, while ample provision should be made for growth. Judgment must be used in this particular. Too much land might be a burden to a new company, or, on the other hand, a valuable investment. It should be level and have a water supply and good drainage. It must have at least one railway connection, and more if possible. For immediate neighbors it is convenient to have other iron industries, for these not only supply the smaller items of raw material, but tend to create a larger labor market. The site should be convenient to the homes of the working men, for, apart from the question of wages, no one thing has a greater influence on the problem of building up a permanent and efficient organization than this.

It is not necessary to discuss all the possible variations that may occur and yet give a satisfactory site, for such things as the shape of the lot, the location and number of railway connections, position of streets, etc., make each site a special study. The necessary, or, at least, very desirable features are:—

(1) Sufficient room to arrange the switches and buildings conveniently, leaving ample room for extensions.

(2) A storage yard at one end of the plant where cars may be unloaded and material stored.

(3) A corresponding area at the other end, smaller in extent, to serve as a storage yard for finished work, with facilities for loading it for shipment.

An Ideal Layout.—Fig. 1 shows an ideal arrangement for a structural shop on a lot of fourteen or fifteen acres, six hundred feet wide and one thousand feet long, lying north and south. A railway, from which switches can be made, is assumed to run along the west side, and a public street at the north end. The outstanding features of this plan are as follows:—

The buildings are placed approximately near the centre of the lot, leaving the ends clear for stock and shipping yards. The office, power-house and template shop, which will have to be of a permanent type of construction, are placed along one side of the lot, where they will not interfere with future extensions of the plant. The storerooms and the smaller departments are arranged along the permanent side of the main building for the same reason. The east side is left clear for additions.

The service tracks are brought in between the buildings so that supplies and materials may be readily unloaded just where required. It will be of great convenience to have two connections with the railway as shown. A double track permits the passage of cars, and gives as well more storage room for them. A cross-over between the tracks will be of great service. One track should be run into the shop under the travelling cranes, so that long and heavy pieces may be loaded directly on the cars. It is very necessary to have easy curves on this, for long girders, loaded on several cars, will be brought out over this track. For this reason, and because heavy locomotives cannot take sharp curves, the degree of curvature should be kept as low as possible. The curves shown have a maximum of 20°, which should be considered the limit. At some future time another track may be put along the west boundary, where cars of the erection department may be stored when not in use.

Regarding the arrangement of the various buildings and departments, it will be noted that the office is placed so as to be the first building approached on entering the plant. Room is left for building on a new front when larger and more elaborate offices are required. The power-house boiler-room and template shop can conveniently be placed in one building, divided by fire-walls, or in a series of buildings. The south end of the template shop may have a temporary end, which will allow it to be extended if necessary, but the power-house and boiler-room should be made of good proportions, as it will not be possible to enlarge these buildings conveniently.

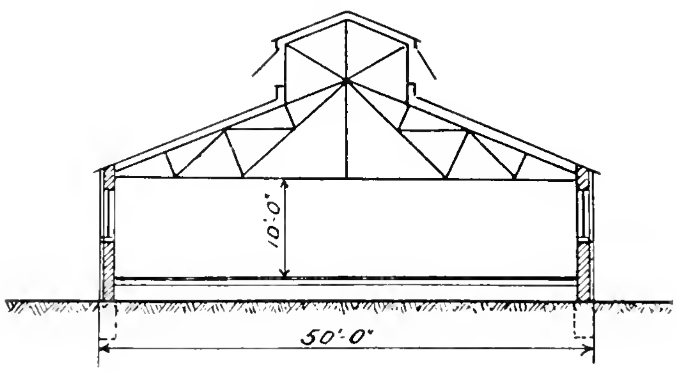
This arrangement places the power-house near one boundary of the site, so that high voltage power lines may be brought into it in such a way that all danger of accident from contact is eliminated. At the same time it is at a central point from which it is convenient to distribute the

power to all parts of plant. A small tower at the north end of the power-house forms the transformer room, and the main switchboard may be placed along the wall between this tower and the engine-room.

As the plant will probably be run by electrical power purchased from a power company and not generated at the plant, the boiler equipment will be largely used for heating purposes only. The buildings requiring heat will be the office, power-house, template shop and machine shop, and these are grouped around the boiler-room so as to make the distribution system very simple.

Templates.—The product of the template shop is used altogether at the south end of the main shop, where the "markers" do the laying out. It will be desirable, therefore, to have the template shop as convenient to the markers as possible, as shown on the plan. It will also be in easy reach of the drawing office, which is over the business office.

On the other side of the tracks, convenient for receiving and shipping (and also at the permanent side of the plant), are placed the storerooms, machine shop, rivet and bolt shops, and the blacksmith shop. These departments are relatively small compared with the rest of the plant, and the space allotted should be quite ample for all requirements. Extensions, however, may be added at either end, and the partitions between these departments may be made of temporary construction so as to be easily re-arranged should it be found desirable to make any changes in the future.



Template Shop

The position of the storeroom, with its platform along the tracks and road in from the street, permits supplies to be readily handled. Its proximity to the machine shop, rivet shop and blacksmith shops will save time in transporting materials to and from these departments. As far as the main shop is concerned, the largest item drawn from the storeroom will be rivets and bolts and those are used entirely by the assemblers and riveters at the north end of the building. The storeroom is made of good size as by far the larger part of the room will be taken up by bulky equipment for the erection department.

The main shop consists of two seventy-five-foot aisles, one for heavy girders and the other for general structural work. As it will be the structural department that will require to be extended in the future, the girder shop is placed next the storeroom and the way is left open for adding two more aisles to the structural shop. Putting the girder shop in this position makes it possible to bring the railroad track into it.

Buildings.—The office building, power house and template shop should be substantially constructed so as to be warm, dry, and fire-proof. The office will be two stories high, the second story being occupied by the engineering staff. The power house and template shop will be a one-story brick building having a monitor, as shown on the cross section, Fig. 2. The roof is of 2-inch concrete carried on steel purlins and trusses. The windows which take up a large part of the wall space, will have steel sash. The monitor windows will be on hinges so they can be opened, and sections of the other windows will also be made to open. The floor of the power house will be concrete. The template shop floor will be raised eighteen inches or so above the ground level and be of 4-inch mill construction with an upper floor of inch white pine. This makes a good floor for laying down work upon.

The type of construction to be followed in the main building is shown on the cross section. A large percentage of the exterior walls as well as the monitors will consist of windows which will insure good illumination throughout. The balance of the wall area will be corrugated iron, with the exception of the eight feet below the first row of windows. This will be made a 9-inch brick wall on the north, west and south sides of the building with a concrete window sill to finish it off. This brick wall will make the building much more comfortable, both winter and summer.

For the roofs of such buildings as are subject to considerable deflection as well as vibration, and shock, it is preferable to use 2-inch matched wood sheeting rather than concrete. As the roof is flat, the covering may be 4-ply felt with tar and gravel.

The frame work will be steel throughout and entirely self-supporting. Steel sash will be used for the windows, as it is only by its use that the large windows can be had.

In dimensions the main building is two hundred feet wide and five hundred feet long. It consists of one fifty-foot and two seventy-five-foot aisles with a sixty-foot transverse aisle at each end. An economical length of bay will be twenty feet. The clearance between the bottom chord of the truss and the floor in the seventy-five-foot aisles should be twenty-one feet to allow for air hoists, etc. In the transverse aisles and the girder shop additional head room will have to be provided to allow for travelling cranes. By making the roof at these points as high as the roof on the monitors a good appearance will be obtained. In the machine shop aisle, fifteen feet will be sufficient clearance. Too much height here means a more difficult building to heat, and longer belts for belt-driven machinery.

All trusses whose bottom chords are at the fifteen and twenty-one-foot level should be designed to carry two five-ton trolleys without danger. Use a factor of safety of five for one trolley and of three for two trolleys. For the roof live load at least fifty pounds per square foot should be provided for and, for certain localities where the snow fall is unusually heavy, the live load should be increased. Where there is any possibility that a column will have to carry a jib crane, provision should be made for it in the original design. This refers to the columns in the girder shop where those along the west wall will have to take radical reamers, while five-ton travelling jib cranes for riveting machines have to be supported by the east side. Particular care should be taken with the design of the bracing for the building, and the bottom chord system should be especially heavy to tie the whole structure together rigidly.

To facilitate the transfer of material from one aisle to another the interior columns in the structural shop should be so arranged that the bottom chords of the trusses form one continuous trolley runway from one aisle to another. This is done by spacing the columns forty feet centres and placing them in the middle of a bay, carrying the roof trusses on longitudinal trusses between these columns. The east wall is filled in with temporary columns to carry the girts

and siding. These can be moved further east when another aisle is added.

It will be necessary in order to attain economy in shop work, to floor the main building. All things being considered, it will be found that a wood floor will be comfortable for the workmen, reasonably durable, easily repaired, and as cheap as any in first cost. On account of the enormous loads the floor will have to sustain and the rough usage it will receive, it should be made of 3-inch red or white pine. Nailing pieces or stringers of 4 x 4 timber should be bedded in cinders thoroughly rammed and smoothed flush. These pieces should be spaced from three to four feet apart. Every precaution should be taken to keep the sub-floor perfectly dry and if there is any possibility of the wood getting damp, it should be treated with some kind of preservative before laying.

Machinery Equipment.—The machinery equipment of the plant is probably the most important question to be considered. Not only does the output of the plant depend on it, but a large proportion of the capital of the company may be invested in equipment and, unless every department is nicely balanced, more or less of it may be unproductive much of the time.

The manufacture of structural steel work requires in its operations the straightening, cutting, shearing, punching, assembling, reaming, riveting, milling and general finishing of a large number of different steel sections.

It would, therefore, be necessary to provide at least machinery for these operations. But the capital invested in a manufacturing plant is subscribed with the expectation of it being able to turn out a certain amount of work which will net a certain percentage of profit. So it will be necessary to have enough machines of each kind to make the capacity of the plant what is desired. For reasons mentioned above, the proportion of each class of work varies widely with different contracts. It therefore becomes a matter of experience and judgment to fix on the amount of equipment to install, as the most careful figuring is at best very approximate. The first item which it is well to fix is the number of riveting machines required. From this the number of punches may be decided upon, and the rest of the equipment proportioned accordingly.

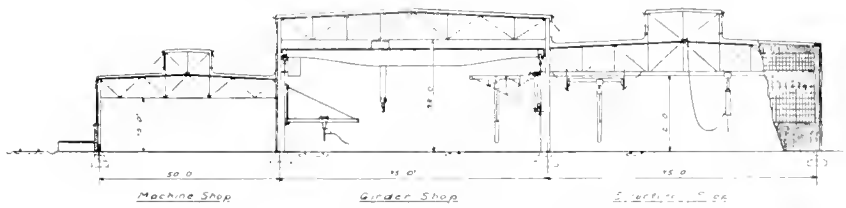
In purchasing machinery certain general rules should be observed. It will be found advantageous in the long run to buy machines having a rated capacity well above the average demand that will be made upon them. Besides the fact that the heavier machine will be more durable, it will in some cases give the plant equipment for a wider range of work at comparatively little extra cost. At the very least it will provide for an emergency which otherwise might prove very expensive.

If the demand for a certain machine product varies widely it will some times be found economical (when the cost of operating a large machine is high) to have two smaller machines instead of a single large one, the first with sufficient capacity for the average requirements and the second capable of taking care of the extraordinary demands. As the plant spreads out, duplicate machines may be required at different locations, it being cheaper to operate two machines than to transport material long distances to have work done upon it.

While complicated machines are to be avoided, it will save capital at the start to buy machines that may be changed over for different classes of work, provided they are not in constant use. For example, the plate rolls should be made a combination of bending and straightening types. The punches should be made so that either cross-cutting or splitting shear blades may be put on to replace the punch and die. The light riveting machine should have one or more extra interchangeable stakes to be used for column or other special work. In this way, at the cost of the extra parts and the time it takes to make the change, work could be done that would otherwise require two separate machines, one of which would probably be idle most of the time.

The matter of punches, shears, reamers, riveting machines and other machines might be taken up at this stage. Their capacities, accessories and other outstanding features are in line for careful attention, but the discussion of these items is a little removed from the province of this preliminary investigation of the general lay-out itself, and will not be discussed.

Arrangement of Machinery and Routes for Material.—The arrangement of the machinery and the establishing of the routes for the material to pass through the shop is one of the most difficult and perplexing problems in connection with the design of a structural steel plant. In theory the material should enter one end of the shop and pass through it from one department to another, emerging at the other end as finished product, without having once been turned around or carried back over any part of its route. In practice, however, there is such a variation in the order in which the work has to be performed—due to details of design and special requirements—that no fixed route can be maintained. At best a material route can be laid out only in a general way, observing the following principles:—



Section on AB see Drawing

Arrange the plant for that class of work which promises to be the most plentiful. If it is necessary that some material be re-handled, let it be the shorter and lighter pieces rather than the long heavy ones.

Sufficient space, sixty-five to seventy feet in the longitudinal direction of the shop, should be left between machines so that, under ordinary circumstances, there will be no crowding or interference. Material over seventy feet in length may be considered very unusual and when, on rare occasions, it becomes necessary to take care of it, more or less difficulty and interference may be permitted. To design the whole plant for it would add very materially to the cost of buildings, while the increase in the distances that the shorter material would have to be transferred would add to the cost of operation of the plant on regular work.

The material will be sorted out in the stock yard and any with kinks or sharp bends in it will be taken directly to the straightener or plate rolls as the case may be. It will then be put on the trucks, taken into the shop and piled on the markers' skids. From here it will be taken to the various cutting machines, and then on to the punches. As it is punched it will be stacked up until required for assembling, when the various pieces are bolted tightly together, taken to the riveters and riveted up. Reamed work will, of course, be reamed before riveting. The work may now be finished up, cleaned and painted, and as soon as the paint is dry it is ready to ship.

A study of Fig. 1 will show that the machines and department are arranged approximately in the order mentioned above, starting at the south end of the plant. Variations from this rule are due to physical limitations, or are the result of experience.

(To be continued.)

NEW STEEL PRODUCTS COMPANY

Several Canadian steel industries are to be merged as the Steel Products of Canada, Limited. The participating firms are the Gananoque Spring and Axle Company, Limited; the D. F. Jones Manufacturing Company, Limited, of Gananoque, and the Dowsley Spring and Axle Company, of Chatham, Ont.

The capitalization of the new company is as follows:—

Six per cent. bonds	$600,000
Preferred stock, 7 per cent.	750,000
Common stock	750,000
	$2,100,000

Seventy-five per cent. of the securities in the new company has been taken in lieu of cash by the holders of stock in the amalgamated companies, and that the rest will shortly be offered to the public for subscription, by Messrs. Richardson and Company, of Montreal.

Mr. W. T. Sampson, for many years manager of the Gananoque Spring and Axle Company, will act as managing director of the new company. His long association with the Jones Company and the Chatham concern, the latter of which was a subsidiary of the Spring and Axle Company, render him particularly well qualified to direct the Steel Products Company, and the future of the consolidation is looked upon as exceedingly bright.

The Gananoque Spring and Axle Company has been engaged in the manufacture of steel springs and axles for upwards of fifty years, while the Jones Company has been in existence for an equally long time, and is among the foremost concerns of the Dominion manufacturing shovels and other steel specialties. The Chatham company is a comparatively recent organization.

RUBBER FROM COKE-OVEN GAS.

A recent issue of the "Bulletin" of the French Society of Civil Engineers contained a paper on "Coke-Oven Gases and Their Utilization," by M. Gouvy, in the course of which he refers to a new application of coke-oven gas, viz., the manufacture of artificial rubber. M. Gouvy points out that after prolonged investigations conducted by various chemists, with the object of finding a substitute for india-rubber, it was produced synthetically by the processes patented by Bayer & Company, of Elberfeld, which were based upon the manufacture of butadeine. More recent researches, however, have shown that rubber consists mainly of a hydrogen carbide, most complex in composition, viz., isoprene, the simplest form of which is butadeine. This having been shown to exist in small quantities in the crude gases of coke ovens, the above-named company based their process upon its polymerization into isoprene, i.e., rubber. The raw material is really extracted from coke ovens by a special treatment of benzol, which distills below 25 deg. C. The manufacture of artificial rubber by this process is still in the experimental stage, and the cost price must be very high, but M. Gouvy thinks it may be reduced.

TIDAL WATERS AS A SOURCE OF POWER.

By C. A. Battiscombe.

At a meeting of the Society of Engineers (Incorporated), held on Monday, May 5th, a paper on "Tidal Waters as a Source of Power" was read by Mr. C. A. Battiscombe, the object of the paper being to draw attention generally to the commercial possibilities of hydro-electric installations in the British Isles, more particularly with regard to the use of the tides. After some introductory remarks in reference to tidal intervals and the range of neap tides, the author points out that in this connection the head of water available for actuating turbines cannot exceed one-third of the range of minimum tides. The form of installation required for a continuous output of power is then discussed, the chief objections to twin installations, so placed that the tidal interval at the one will not synchronize with the tidal interval at the other, being pointed out. An outline is given of the arrangements proposed for the constant maintenance of a working head, by means of a chamber for the turbines, connected by valves to the tidal way and to three reservoirs in which the tidal water may be impounded, and to this is added a description of the proposal of sequence of flow between the tidal way and the reservoirs.

It is claimed that the utilization of the tides for power purposes presents few engineering difficulties as far as principles are concerned, but that the real difficulty lies in the question of cost, and therefore in the choice of the site and in the design of the structural details.

The expenditure on commercial works that an engineer is justified in recommending is suggested, and some explanatory remarks are offered in respect to various items given in the rough estimate and to the principles governing the economical capacity of a proposed installation for any range of tide. The rough estimate follows next and the cost of the Board of Trade unit, obtained from the proposed installation, is then considered from the point of view of supply and demand, both from a commercial and a municipal standpoint, on the basis of annual expenditure over a period of fifty years. The paper concludes by insisting on the importance of regarding the supply of fuel as a matter that concerns the whole nation; that the demand for combustible fuel is continually increasing, and that coal being practically the only fuel found in England, it would be mere folly to neglect any other available source of energy whereby the present rate of consumption of coal may be sensibly reduced. It is submitted that not only can the tides be utilized as a constant source of power, but that, taken in conjunction with the power that could be derived from fresh-water rivers, their utilization would be a great gain to the commercial and industrial interests of the United Kingdom.

MOOSE JAW ELECTRIC RAILWAY COMPANY.

The gross receipts of the Moose Jaw Electric Railway Company amounted to $77,996 for the past year; 1,607,770 passengers were carried. The assets of the Moose Jaw Electric Railway are placed at $573,367, of which $570,128 is in plant, property and equipment, and the balance of $2,239 is in accounts receivable. The liabilities are: capital stock (paid up), $480,271; bills payable, $15,359; accounts payable, $22,581; and a profit and loss surplus of $15,359. The company's officers and directors are: president, Mr. A. A. Dion; vice-president, Mr. Newton J. Kerr; secretary-treasurer, Mr. D. R. Street, and Messrs. E. J. Daly, E. O'Connor, T. Frank Ahearn, P. B. Mellon, A. H. Dion and Charles E. Armstrong.

CONTENTS OF THIS ISSUE.

FACTORS IN PLANT DESIGN.

As one of the earliest factors of industrial economy, as applied to factory construction and operation, there is no more important phase open for thorough consideration than a complete summary of the many demands which will be made upon the building after erection. A careful routing of work from its raw state until it reaches the siding, both these initial stages being included in the study, means much toward low operating cost throughout the years during which the plant will be in service. Such items as location, market, cost of labor, power, arrangement of buildings and machinery, and future extensions, if given most careful study in the early stages of design, frequently minimize operating expenses to such a degree that if computed over a number of years, would vindicate a thorough initial investigation running into a considerable sum.

In his article dealing with a design of a structural steel plant, Mr. Darling gives adequate attention to this phase of engineering design, and clearly cites the advantages to be derived from ample provision for conditions bearing upon the efficient housing of an industry.

THE MASS CURVE IN DETERMINING STREAM FLOW YIELD.

It is only very recently that the mass curve has been used to determine the yield of a watershed. The maximum quantity of water which can be obtained daily throughout the driest cycle of years covered by the records is exceedingly difficult to obtain if it is attempted to secure the information by numerical means. The mass curve furnishes a ready and convenient method of analyzing the flow of a stream, and it is rather surprising that it has not been more widely used. This curve or diagram is used for computing the yield of a watershed from a continuous series of gaugings, and at the same time for determining the volume of reservoir capacity required to store the flood waters for use in season of drought so as to maintain a specified constant rate of flow. The method was first described by Mr. John R. Freeman in his report on New York's water supply.

Briefly, the method consists in adding up the totals of the daily or monthly yield from month to month for the whole period of gaugings under consideration, then plotting the successive steps of accretion of the mass as an irregular line or mass curve. Any desired rate of draft may then be assumed, and its successive sums plotted to the same scale, and of a uniform rate. This draft curve forms a straight, inclined line, and if it is made to start coincident with some point or summit on the mass curve, the divergence of the two curves at successive points serves to show the volume of storage that would have been required on this date to have maintained the required rate of flow up to that time.

A very interesting paper in which this mass curve method was used extensively is one read recently before the Western Society of Engineers by George L. Thow and L. R. Howson. In this paper the various steps in the computation of yield on the Hickman Creek watershed, run-off records of which are available for a period of twenty-six years, are analyzed. This discussion will well repay careful study by the hydraulic engineer interested in the study of stream flow. The increase in acreage of drained agricultural lands will steadily increase the run-off and continue to lower the level of the ground water. With the exhaustion or full development

of ground water supplies, the impounding of rainfall in reservoirs will be necessary.

One of the most significant conclusions drawn from the above paper is the vital importance to be placed on the length of the run-off record. This is well shown by a few figures from the paper. With an available storage equal to 12 inches on the watershed a daily yield of 3,600,000 gallons per day could be obtained. Let us suppose the record ended with 1902, covering a period of eighteen years from 1885 to 1902, inclusive. During this period the driest cycle of years occurs from 1889 to 1902. Assuming the same amount of reservoir capacity available as above, we find a daily yield of 4,300,000 gallons per day could thus be obtained.

Selecting the period from 1888 to 1898 from the record, we have eleven years during which time, even in the driest years, 1894-95, a daily yield of at least 5,800,000 gallons per day could be obtained, based on 12 inches of storage available.

These facts show very conclusively that by using a record of short duration some very erroneous conclusions as to the least yield might result. The following tabulation, taken from the paper, shows clearly the value of the length of a run-off record in the computation of yield:—

Length of record.	Least yield during driest cycle.	Per cent. based on 26-year record.
Twenty-six years	3.6 M.G.D.	100 %
Eighteen years	4.3 M.G.D.	120 %
Fifteen years	4.5 M.G.D.	125 %
Eleven years	5.8 M.G.D.	160 %

Even with a record with 26 years of run-off data available, it cannot be safely assumed that a drier period has not existed previous to those records, or may not again occur at some future time.

THE INTERNATIONAL JOINT COMMISSION.

In *The Canadian Engineer* for May 1st and 8th we commented editorially upon the Livingstone Channel in the Detroit River, since the opening of which, last October, the town of Amherstburg, Ontario, had raised strong objection to the proposal to construct a dam at Bois Blanc, the purpose of which was to maintain the normal depth of water in the river above the channel. The objection brought forward by Amherstburg was that the proposed dam would divert a large body of water into the narrow channel between the town of Amherstburg and Bois Blanc Island, increasing the current to such an extent as to render the harbor practically useless. It was further predicted that the ice brought down by this increased flow would destroy docks and personal properties along the water front. There was also the danger to health from Detroit City sewage, which would be diverted in proximity to the shore at Amherstburg.

The commission handled most admirably the test consigned to it. In conclusion, it deemed necessary the erection of a dyke for the improvement and safety of navigation, but that such, if built on the west side of the river instead of adjacent to Amherstburg, would reduce the velocity of flow to the desired degree, at the same time not affecting the flow in the Amherstburg channel. Its recommendation to the Governments of both countries was that a dyke be built upon this location; and further, that considerable excavation work be executed on the west side of the Livingstone Channel, and that the shoals on the east side be also dredged.

A SEWER DISCHARGE DIAGRAM.

By J. M. M. Greig, A.M.I.C.E.*

[Thinking that many of our readers who are interested in sewer design and construction might care for an extra copy of the diagram accompanying this article, we have had a few extra copies struck off on coated stock, on the back of which is given the formula to be used in connection with it. Engineers who would care to receive a copy of this diagram may do so by asking for it—*Editor.*]

The author compiled the accompanying diagram to assist in arriving at the best form of sewer for each particular case, or rather to give a choice of several sizes of sewers with equal discharging capacities.

The diagram is arranged to show the discharge in cubic feet per second of circular brick sewers, egg shaped brick sewers, concrete culvert shaped sewers of the type illustrated, and vitrified pipes when running full at any gradient. It also gives an indication of the velocity of flow in the concrete culvert types, but these velocity curves do not hold for the brick sewers.

The formula used was:—

Discharge in cu. ft. sec.—$A\ C\ \sqrt{R}\ \sqrt{S}$

Where A = Sectional area.

C = Kutter's coefficient for different values of $\sqrt{R}$ and N (taken from Wollheim's sewerage note book).

R = Area divided by wetted perimeter.

S = Slope.

N = Coefficient of friction—.015 for brickwork and .013 for concrete.

The value $AC\ \sqrt{R}\ \sqrt{S}$ was obtained for each cross section of sewer for a gradient of 1. in 100 and having got together these amounts the diagram was constructed as follows:—

The slopes whose square roots equalled 0.001, 0.002, etc., up to 0.1 were marked down at equal distances along a horizontal line from the origin towards the right and a vertical line was erected at 0.1, that is, at the 1 in 100 slope. On this vertical line a scale of discharges was marked off. Then the value of $AC\ \sqrt{R}\ \sqrt{S}$ previously obtained for each particular size of sewer was noted on the discharge scale and lines were drawn from the origin through these points and on these lines produced the dimensions of these sewers were written above a short length of line. The radial lines drawn on the diagram are through every 50 cub. ft. sec. at 1 in 100 and are merely guides to the eye but by fixing a thread to the origin a convenient straight edge is formed which can be used in finding the following:—

The various sizes of sewers which will give the required discharge at a certain gradient, the discharge any sewer gives at any gradient, or the gradient required to give a certain discharge with a particular size.

If size is required stretch the thread over the intersection of the gradient and discharge lines and the dimensions can be read above the thread on the right of the diagram as, for instance, at 1 in 400, 300 c.f.s. may be got through concrete culvert of 5′ 6″ x 8′ 9″ or 6′ 6″ x 7′ 3″ or a 7′ 3″ diameter brick sewer.

If discharge is required stretch the thread along the line of the particular size of sewer chosen and read the discharge where the thread cuts the gradient line.

If gradient is wanted stretch the thread along the line of the sewer and read off gradient where the thread cuts the discharge line. The discharge scale on the larger diagram for the pipe sewers shown thus: (12) is 100 times that for the larger sewers, that is the figure 1,000 on the 1 in 100 line for an 18″ diameter pipe must be reduced to 10. c.f.s.

CONCRETE CULVERTS.

By F. H. McKechnie, B.A.Sc.

Introduction.—The distinction between bridges and culverts is not a hard and fast one, although Webb, in his book on railroad construction, attempts to define the term "culvert" as follows: "The term culvert may be applied to all water channels passing through railroad or highway embankments, which are not of sufficient magnitude to require a special structural design, such as is necessary for a large masonry arch or truss bridge." This seems to be rather a mistaken idea of culverts which is much too frequently met with, that, given a standard design or two for culverts, all that is necessary is to choose which design to use and put the culvert in place. Such a method of choosing the culvert should only be used where all the conditions for the foundations are perfect, such as rock bottom, in which case perfect stability of foundation is assured.

There are a number of things it is important to consider before deciding ou size, style or shape of culvert to be used.

Waterway Area.—Where no reliable data in reference to the volume of water flowing through a culvert opening is obtainable, the culvert area may be computed approximately by a number of empirical formulae. Among these is Myer's formula, which is as follows: The required culvert area is equal to the square root of the drainage area in acres, multiplied by F, where F is a coefficient varying from unity, for flat country, to four, for rolling or mountainous country from which rainfall is discharged at a greater velocity. The proper value for the coefficient, for any particular location, must be selected entirely by the judgment of the engineer.

Talbot's formula is another in common use: Area of waterway in square feet is equal to C, a constant, into the fourth root of (the drainage area in acres)^3 cubed. For steep and rocky ground C varies from two-thirds to one. "For rolling agricultural country, subject to floods, and with the length of the valley three or four times its width, C is about one-third. In other districts, not affected by accumulated snow, and where the length of valley is several times the width, one-fifth, one-sixth, or even less may be used."

Formulae such as these two given depend very largely upon the choice of coefficient so that they are valuable, chiefly as a guide to the judgment, rather than hard and fast rules to be followed. They indicate a probable maximum and minimum between which the true result may lie.

On the legal side of the subject Engineering Record says in part: Although courts have ruled that the railway companies are not to be held liable for insufficient capacity for extraordinary floods, there is too much guess work in determining sizes of such openings. It is easy to establish better procedure for selecting the cross sections of culverts than exist in some railways. The main factor is the shape of the drainage area and another, quite as important, is the topography, also the effect on the flow of the character of the soil. This factor rarely receives the attention it should. A naturally impervious soil is rendered practically impervious by a rainfall of half an hour and so will yield a much larger run-off toward the end of a heavy storm than one that is very sandy. A very wet marsh will also yield an extraordinary run-off in a heavy storm. There are good formulae, but one suitable for prairie is not suitable for hilly country. While a railway may be exempt from damages, due to extraordinary freshets, the courts will hold it strictly to account where the channels are inadequate to carry off the water that may be reasonably expected.

The following decision was given in the case of the Southwestern Railway versus McKay, for injury to property on account of flooding: "It is the duty of a railroad company to provide proper and sufficient openings or culverts for the escape of water of all streams crossing its roadbed, so as not to flood the land of other riparian owners, whether at ordinary stage of the water, or during floods which could reasonably have been guarded against, and if it fails to provide such openings it is liable to any person damaged thereby."

Where there is no previous knowledge of the country and there are no records which could be of assistance in determining the flow, one of the safest plans is to build a temporary trestle, which will not only provide an ample waterway for all floods during its life, but which will permit of the construction of a culvert of proper dimensions under the trestle with the least possible interference with the construction of the culvert. The life of such a trestle would be sufficient to determine the area required closely enough.

Placing the Culvert.—In building a culvert it is not always necessary to place it in the old stream bed, in fact it is often very wise to choose an entirely new spot for the stream and culvert. The culvert should be placed in such a position that the water will come to it as directly as possible, and will have the best possible channel away from it. For this purpose the stream may be diverted and cleaned out above and below the culvert opening, giving all the advantage for the culvert of a clear entrance and exit for the water.

Except where such a condition is impossible of realization, a culvert should be placed at right angles to the centre line of track, on account of the great saving in the quantity of the material used, the improvement in its appearance and from the fact that in the skew culvert new stresses may arise on account of the different position of the structure with respect to the embankment.

Foundation Bed and Foundations.—Careful soundings should be taken before locating the culvert and the result of the soundings should, in a large measure, determine the character of the culvert to be used, whether plain or reinforced. Patton says, in his treatise on foundations: "When structures fail, it may in general be said, that it is impossible to determine the cause, but in a large majority of cases, it can be traced to that part of the structure under ground or under water, and ultimately due to the failure of the foundation bed. For even if the part of the structure under ground is defective in some of its parts, it throws an excessive weight on some part of the foundation bed. Be sure of your foundation bed and foundation and except in extreme cases the upper part of the structure will take care of itself."

It is usually perfectly safe to build any culvert required on material which can be called rock. Boulders or gravel or hard pan can also be called reliable for ordinary structures under good conditions. The scouring action of water should be avoided in all cases. Confined sand is safe to bear a load of any amount as long as it is confined and running water is kept away from it. Taken in general though, sand is not a very satisfactory foundation. Compact and dry clay will carry very large loads, but it is very soon rendered useless by contact with water, as it is then a pasty material and gives away by flowing and bulging up around the structure.

Trautwine says, that on good compact gravel sand or loam, at a depth below atmospheric influences, two to three tons per square foot are safe. Pure clay, especially if damp, should not be trusted with more than one to two and a half tons, according to the case. Examples will be given, in a later part of this paper, showing effect of different conditions of foundations, on actual culverts in the field.

Typical Specifications for Concrete Structures.—From Ontario Government Highway Report, 1911:

(1) The general type of highway bridge shall preferably be as follows, but limiting lengths are not absolute and may be varied as occasion permits.

(a A concrete arch, or concrete abutments with slab covering for spans up to sixteen feet.

(b) A concrete arch or concrete beam bridge for spans sixteen to forty feet.

(c) A concrete arch for spans exceeding forty feet in length.

(d) All concrete structures will preferably be reinforced, using medium steel.

(2) All parts of the concrete shall be proportioned so as not to exceed the following unit stresses, in pounds per square inch for stone or gravel concrete:

Extreme fibres of beams and slabs, for bending......	650
Shearing stress in concrete	60
Bond between plain steel and concrete	60
Bond between deformed steel and concrete	100
Tension in soft steel	14,000
Tension in medium steel	16,000
High steel, one-half the elastic limit, but not exceeding	20,000

(3) Reinforced concrete beams and slabs will be designed on the assumption that compressive stresses may vary directly as the distance from the neutral axis. No allowance will be made for concrete in tension. Ratio of moduli of elasticity of steel and concrete will be assumed as fifteen. All calculations will be based on concrete having a crushing strength of two thousand pounds per square inch in twenty-eight days.

(4) The bearing power of soils under foundations shall, if possible, be based on actual test, but where this is impracticable, the following shall be used:

	Tons per sq. ft.
Rock in thick beds	25
Strong gravel and coarse sand, dry	8
Compact sand or firm clay, dry	4
Clay, moderately dry	2
Clean, dry sand, not cemented	2
Wet clay	1
Quicksand and wet, yielding soils	0 to ½

(5) The safe bearing power of wooden piling, determined by the following: $P = \dfrac{62wh}{s-1}$

Where P = Safe load in pounds.
W = Weight of hammer in pounds.
H = Fall of hammer, in feet.
S = Penetration of last blow, in inches.

(6) Each structure shall be designed to carry the following loads:

(a) A dead load consisting of the total weight of concrete steel and other material therein, including the weight of earth or other superimposed filling; the weight of the concrete to be assumed at one hundred and fifty pounds per cubic foot, and earth fill at one hundred pounds per cubic foot.

(b) A uniform load, expressed in pounds per square foot of floor surface, covering the whole or any part of the bridge.

(c) A concentrated live load expressed in tons, passing over any portion of the bridge, on two axles at ten-foot centres and six-foot gauge, two thirds of the load to be carried on the rear axles.

(d) For floor slabs, a concentrated load expressed in pounds midway between stringers or beams and resting on a base one foot wide.

Materials.—Cement must be of a known brand of Portland cement, approved by the engineer in charge of the work, and complying with the requirements and tests of the Canadian Society of Civil Engineers, for cement.

Fine aggregate shall consist of sand, crushed gravel or stone screenings, passing when dry a screen of one-quarter inch mesh; and not more than six per cent. passing, when dry, a screen having one hundred meshes to the linear inch. The material shall be clean, sharp, siliceous and of varying sized grain. Gravel, if used in its natural state in making "fine" concrete, shall be of uniform character and varying grain, making a dense and compact mass, such that the smaller particles will fill the voids between the larger, the largest stones therein to be such as will flow readily around the reinforcement but will not separate from the mortar in laying. Gravel shall be free from earthy mould or organic matter. Should there be insufficient fine material to properly fill the voids and make a compact mass, the deficiency shall be corrected by the addition and mixing of such quantity of sand, and in such manner as may be required by the engineer or inspector in charge of the work. Should the gravel to be used contain an excessive amount of sand, loam, large stones or other objectionable material, it shall be screened through a mesh of proper size. Where the sand and fine stuff is thus removed the resulting mass of pebbles shall be treated as broken stone and sand shall be mixed therewith in the manner herein described for broken stone concrete. Where large stones only are removed the material shall be treated in the ordinary manner for gravel concrete.

The steel used for reinforcement shall have an ultimate strength of not less than fifty-five thousand pounds per square inch and must bend cold one hundred and eighty degrees to a diameter of the thickness of the piece tested, without fracture.

The water used is to be clean, and the mixture must be wet enough to flow into the forms and around the reinforcement without permitting the separation of the coarser aggregates from the mixture in conveying from the mixer to the forms. The weight of Portland cement shall be assumed to be one hundred pounds per cubic foot.

Proportioning Materials.—The proportions of materials to be used in mixing fine concrete shall be by measure, loose and unless otherwise directed by the engineer, shall be as follows:—

Gravel Concrete.

(a) Abutments, piers and wing walls: One part of cement to seven parts of gravel.

(b) Arches from the springing line, floor slabs, beams and parapet walls: One part of cement to five parts of gravel.

Broken Stone Concrete.

(c) Abutments, piers and wing walls: One part of cement, three parts of sand, and six parts of broken stone.

(d) Arches from springing line, floor slabs, beams, and parapet walls: One part of cement, two parts of sand and four parts of broken stone.

The specifications given above, while incomplete, cover pretty well the usual specifications required in the building of concrete culverts.

Types of Concrete Culverts in Common Use.

Concrete pipe culverts—plain and reinforced.
Old rail culverts.
I-beam culverts, and box culverts.
Arch culverts—plain and reinforced.

These types of culverts will be discussed in the following pages, with examples of each.

Concrete Pipe Culverts.—Tests of plain and reinforced culvert pipes.*

The tests were intended to throw light on the strength of pipes placed in railroad embankments, and are valuable on account of the practical conditions under which the tests were carried on. The main tests were made with a specially prepared testing apparatus, which included a box of strong, stiff construction, and the pipes were embedded in sand and the load applied through a saddle, resting on a sand cushion. Short rings of concrete and reinforced concrete were tested, both under concentrated load and under distributed load.

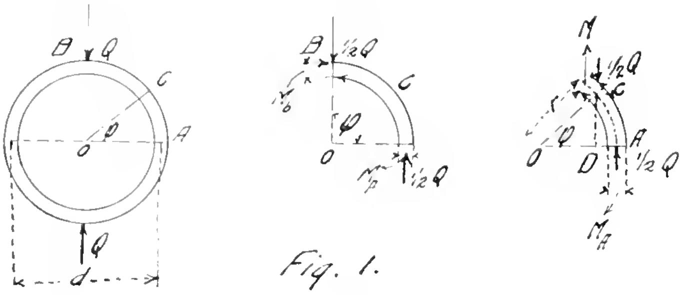

Fig. 1. (a) (b). (c)

Mechanics of pipes and rings subject to external pressure.

Bending moments and conditions of loading: The stresses developed in rings subject to external earth pressure, as in railroad culvert pipes, are dependent upon the bending moments developed, and, as the exact load coming upon the ring and its distribution over the surface are difficult to determine, the bending moment is in general quite uncertain. The amount of the load and its distribution, and therefore the bending moments on different parts of the ring, depend upon a number of conditions, some of them being: the nature of the earth used in filling; the method of bedding the pipe; the way of tamping the earth at the sides; the amount of the lateral restraint or pressure of the earth horizontally; the method of filling and tamping the earth above; the condition of moisture in the earth, etc.

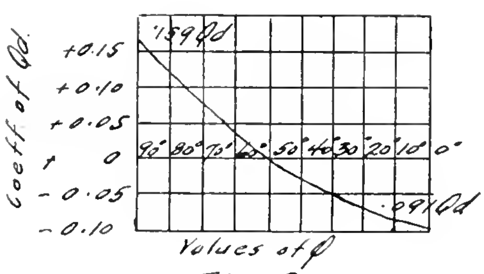

Fig. 2.

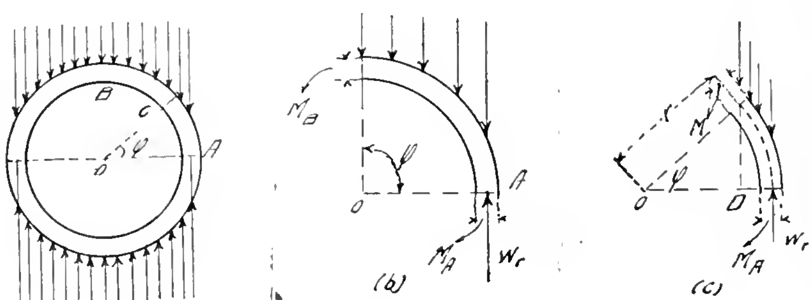

(a) (b) (c) Fig. 3.

Evidentally in such earth as quicksand, the conditions may approach those of external hydrostatic pressure, and on the other hand, in the deep sewer trenches the earth filling may act so that its weight is carried against the sides of the trench. In discussing the stresses in rings, it is well, first, to find the bending moment for certain assumed conditions of loading, then to make tests under varying conditions of loading, and finally to compare these results with a view to determining the probable range of bending moments under the actual conditions of construction. The assumed loadings include:—

(1) A concentrated load at the crown of the ring.

(2) A vertical load distributed uniformly over the horizontal section.

(3) A distributed vertical load together with a horizontal load, distributed perpendicularly over the sides of the ring.

(4) An oblique loading.

On account of the uncertainty in these calculations, the difference of the intensity of the load at the crown and at the extremities of the horizontal diameter, due to the different depths of earth, need not be considered. In general, the pressures on the lower half of the ring will be considered to be the same as on the upper half. As refinements are not essential, and approximations are permissible, the equations will be based on a thin ring of homogeneous material, having a constant modulus of elasticity, and it will also be assumed that the changes from a circular form have little effect on the dimensions of the ring.

For a load concentrated as shown in Fig. 1 a, the quadrant shown in Fig. 1 b will be in equilibrium under the load ½Q at B, a thrust ½Q at A, a moment 0.091Wd at A, and a moment 0.159Wd at B.

At B, M is 0.159Wd. (1)

For a point C at an angle ϕ above the horizontal diameter (Fig. 1 c) the equation for the bending moment is $M = Qd\,(0.159 - \frac{1}{2}\cos\phi)$ (2)

Fig. 2 shows the changes in bending moment between the haunches and the crown. The point of zero bending moment is $\phi = 50^\circ\ 30'$. At this point the sign of the bending moment changes from negative to positive.

The expression for the deflection of the pipe under concentrated load or for the change in vertical diameter is $\frac{0.0186Qd^3}{EI}$ and for the change in horizontal diameter is $\frac{0.171Qd^3}{EI}$.

Distributed Vertical Load.—For a vertical load, distributed uniformly over the horizontal section, as shown in Fig. 3 a, the quadrant shown in Fig. 3 b will be in equilibrium under the load, a thrust at A, a moment at A, and a moment at B.

Calling the load on the ring W, and the mean diameter of the ring d, the moments at A and B, which are equal, are given by the expression $M = 1/16Wd$. (3)

For a point C at an angle ϕ above the horizontal diameter (Fig. 3 c) the equation for the bending moment is $M = 1/16Wd\,(1-2\cos^2\phi)$ (4)

In Fig. 4 is shown the change in bending moment between the haunches and the crown. The point of zero bending is ϕ—45°. At this point the sign of the bending moment changes from negative to positive.

* Tests of cast iron and reinforced concrete culvert pipe, by A. N. Talbot, in University of Illinois Bulletin.

The expression for the deflection of the pipe, or for the change in vertical diameter, is $\frac{1/96Wd^3}{EI}$, and the change in horizontal diameter is the same.

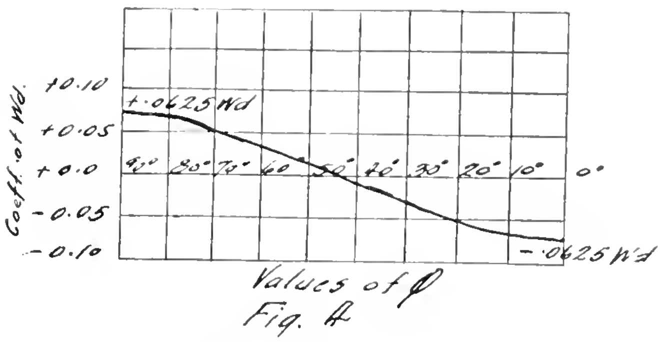

Fig. 4.

Distributed Vertical and Horizontal Load.—If it be considered that the vertical load is uniformly distributed over the horizontal section of the pipe as before, and that there is also a horizontal pressure uniformly distributed against the pipe, the loading will be as represented in Fig. 5 a.

If the ratio of the horizontal pressure to the vertical pressure is denoted by q, the moments at A and B will be given by the equation, $M = 1/16(1-q)Wd$ (5)

For a point C at an angle ϕ above the horizontal diameter (Fig. 5 b) the equation for the equation for the bending moment is $M = 1/16Wd(1+q-2\cos^2\phi-2q\sin^2\phi)$ (6)

The bending moment becomes zero at $\phi = 45°$, as in the other case. If the intensity of the horizontal pressure is the same as that of the vertical pressure, q = 1 and M becomes zero at all points. This corresponds to uniform external pressure, and equal pressure is produced in all parts of the ring.

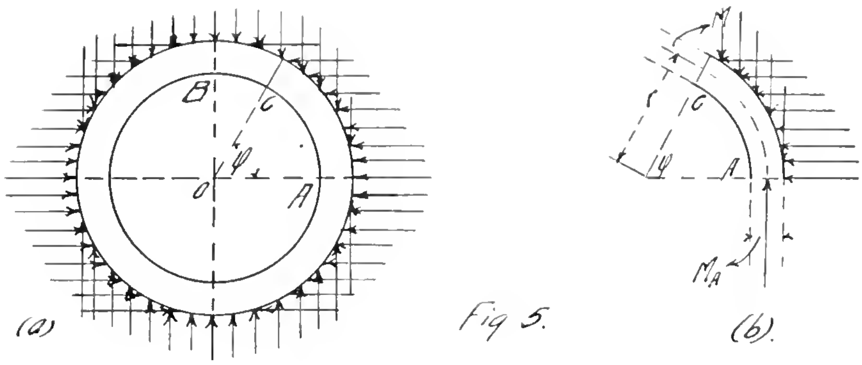

Fig 5.

Oblique Load.—In the case of the concentrated load and the distributed load it is seen that the bending moments at A and B are large, and that the moment decreases to zero amount at some point between A and B. If it was certain that this loading was present, no provision against bending need be made at the points of zero bending moment, and but little for points close on either side. However, it must be borne in mind that if there is a change from the specified loading, the conditions of the bending moment are likewise changed. If, for example, the method of filling over the pipe should be such as to make the pressure come obliquely, as

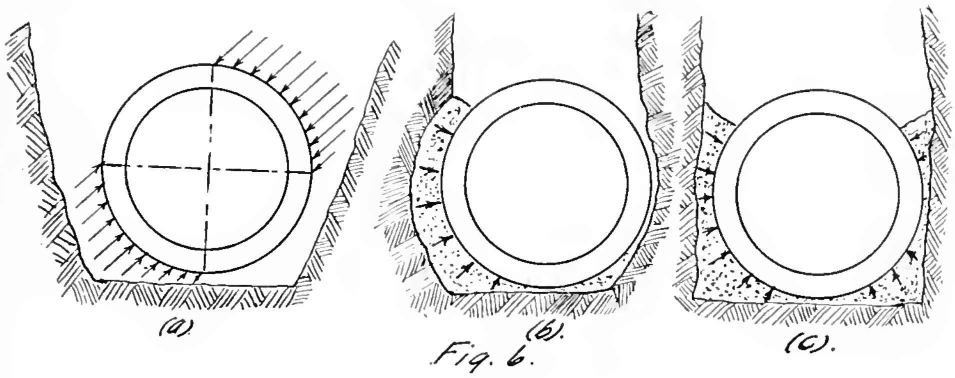

Fig. 6.

shown in Fig. 6 a, the maximum moment would be at the 45° points and the maximum moments at the ends of the horizontal and vertical diameters.

Similarly, if in a trench a slip of earth cau[se] the pressure to come against the pipe, as shown in Fig. 6 b, the the distribution and amount of the bending moment would be very different from that of the usual vertical loading. While an accurate measurement of the bending moments in such cases is impossible, yet in any case it is possible to judge the amount and location of the bending moments, within reasonable limits, and to provide strength in the section of the pipe to take the consequent stresses.

Resisting Moments and Stresses.—With rings whose thickness is small in comparison with the diameter, the difference between the length of the inner and outer fibre is small, and the expression for the resisting moment used for ordinary straight beams may be applied without much error. The length of ring (width of beam) will be considered unity. Call t the thickness of the ring.

For the rectanglar section of the ring the resisting moment will then be $1/6ft^2$ where f is the unit stress at the remotest fibre. In sections where there is no thrust, the maximum stress at the remotest fibre may be found by equating the expression for bending moment and the expression for the resulting moment and substituting the numerical values at the section considered. If a thrust exists at the given section, this thrust may be considered to be uniformly distributed over the section and the stress will be equal to the sum or difference of the resisting moment stress and the thrust stress.

For a concentrated load at the crown (Fig. 1) the stress at B, since there is no thrust, may be determined from the formula $\frac{1}{6}ft^2 = 0.159Qd$ (7)

At A, the same form of expression may be used for the resisting moment, but this must be combined with the stress due to the vertical thrust. Considering this to be uniformly distributed, the stress in the remotest fibres will be

$$F = \frac{Q}{t} + \text{ or } - \frac{0.091}{\frac{1}{6}t^2} \quad (8)$$

The minus sign will be used for the outer fibre and the plus sign for the inner fibre. At any point C (Fig. 1 c) the stress at the remotest fibre may be shown to be

$$f = \frac{\frac{1}{2}Q\cos\phi}{t} + \text{ or } - \frac{M}{\frac{1}{6}t^2} \quad (9)$$

For a uniformly distributed horizontal load the stress at the crown B will be $f = \frac{1/16\ Wd}{\frac{1}{6}t^2}$ (10)

and at A, $f = \frac{1}{2} + \text{ or } - \frac{\frac{3}{8}Wd}{t^2}$ (11)

and at any point C, (Fig. 3 c) $f = \dfrac{Wr\cos^2\phi}{t} + \dfrac{M}{\frac{1}{6}t^2}$ (12)

For a distributed vertical and horizontal load (Fig. 5) there will be a thrust both at A and B. The stresses at the crown B, will be given by the equation

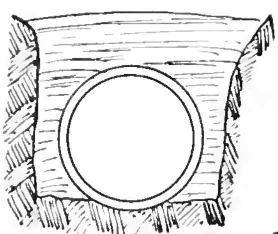
$$f = \frac{QW}{t} + \text{ or } - \frac{MB}{\frac{1}{6}t^2} \qquad (13)$$

At A, the extremity of the horizontal diameter

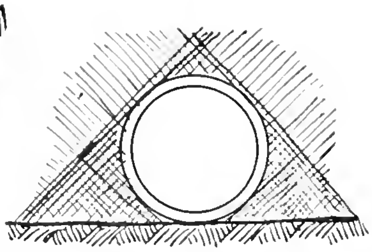
$$f = \frac{W}{t} + \text{ or } - \frac{MA}{\frac{1}{6}t^2} \qquad (14)$$

At any point C, (Fig. 5 b) the expression for the stresses may be written $f - = \dfrac{W\cos^2\phi}{t} - \dfrac{qW\sin^2\phi}{t} + \text{ or } - \dfrac{M}{\frac{1}{2}t^2}$ (15)

These formulae may be applied without any great error to plain concrete rings at the breaking loads, if the modulus of the materials for rupture, obtained under the same conditions of thickness and loading, be substituted for the maximum tensile stress f. For a reinforced concrete ring the conditions are somewhat different from the above. For ordinary cases the bending moment, determined as above, and the resisting moment of the reinforced concrete section may be equated.



8(a).



8(b).

The amount of the tension in the steel at the point A, may be calculated by the formula $f^1 = \dfrac{f - \frac{1}{2}nT}{t(1+np)}$ (16)

The formula is applicable for both concentrated and distributed loads. In this formula f is the tensile stress in the steel due to the bending moment, p is the ratio of the area of reinforcement for a unit width of beam to the distance between the centre of the steel and the compression face of the concrete. T is the thrust or pressure against the face of the section, and n is the ratio of the moduli of elasticity of steel and concrete, and equal to fifteen for the experiment. t is the distance from the compression face to the centre of the steel reinforcement.

In the actual tests on pipes the following results were obtained:—

Concentrated load tests: The plain concrete rings broke before there was an appreciable deflection, so no measurements of deflections were made.

The reinforced rings deflected considerably before final failure. At a load of from 1,000 to 2,000 pounds per linear foot fine cracks appeared on the tension face, generally the top or bottom. When higher loads were applied, numerous cracks appeared on the tension faces at the top, bottom, and sides. Two forms of critical failure were seen; one a tension failure of the reinforcing bar at the top or bottom of the ring, and the other a failure of the concrete by the stripping of the concrete from the tension face.

Distributed load tests of reinforced concrete rings: In the reinforced concrete rings cracks appeared early in the test on the tension side at the top and bottom, but the load continued to increase to a load of 15,000 pounds per linear foot. The reinforced concrete rings were much stiffer than the plain concrete rings.

Distributed load tests of plain concrete rings: The plain concrete rings, tested under a distributed load, cracked at the top, bottom and sides at an early load. Later when sufficient side restraint developed the load increased until a considerable difference was shown in the horizontal and vertical diameters.

The critical strength of reinforced concrete culvert pipe where the reinforcement does not exceed, say, 0.75 of 1 per cent., and is of medium steel, may be measured by the resisting moment calculated by the ordinary beam formula. The resistance against diagonal tension and stripping of the concrete over the bars, may be improved by flattening the arc around the top and bottom.

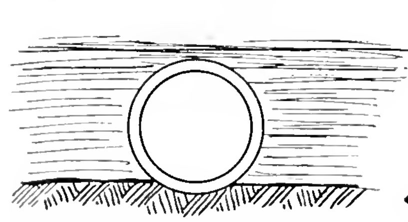
Bedding and loading of pipes: If the layer of earth immediately under the pipe is hard or uneven, or if the bedding of the pipe at either side is soft material or not well tamped, the main bearing of the pipe may be along an element at the bottom and the result is in effect, concentrated loading. This condition may be aggravated in the case of a pipe with a stiff hub or a bell where settlement may bring an unusual proportion of the bearing at the bell and the distribution of the pressure be far from the assumed condition.

In case the pipe is bedded in loose material the effect of settlement will be to compress the earth immediately beneath the bottom of the pipe more completely than will be the effect at one side, with the result that the pressure will not be uniformly distributed horizontally.

In case a culvert pipe is laid in an ordinary embankment by cutting down the sides slopingly, as shown in Fig. 8 a, it is evident that the load which comes upon the pipe will be materially less than the earth weight immediately above it.

In a case where a culvert pipe replaces a trestle and the filling is allowed to run down the slope, as shown in Fig. 8 b, the direction and amount of the pressure against the pipe will differ considerably from that which obtains in a trench or in a case of level filling, shown in Fig. 8 c.

It is possible in this case that the smaller amount of settlement of the earth directly over the culvert pipe, due to the greater depth of earth on adjacent sections, may allow a greater proportion of the load to rest on the culvert pipe than



8 (c).

would ordinarily be assumed. It should be noticed that the distribution of the pressure by means of earth under and over a ring assumes that the earth is compressed in somewhat the same way as when other material of construction is given compression. Unless the earth has elasticity, the distribution of pressure cannot occur. To secure the uniform distribution assumed, the ring itself must give enough to allow for the movement of the earth which takes place under pressure. This is especially true with reference to the presence and utilization of lateral restraint, and a ring which does not give laterally, as for example, a plain concrete ring will not develop lateral pressure in the adjoining earth under ordinary conditions of moisture and filling, to any great ex-

tent. As the conditions of earth and moisture produce mobility and approach hydrostatic conditions, the necessity for this elasticity and movement do not exist, but here the lateral pressure approaches the vertical pressure in amount and the bending moments become relatively smaller.

The importance of care in bedding culvert pipes is shown and also the necessity for care in filling over them and there is also great difference of bending moment developed with different conditions of bedding and filling. Where strength is needed, time will be well spent in taking care in the bedding of the pipe and filling around and over it. A little additional labor will add considerable stability, life, strength and safety to such structures, far out of proportion to the added cost. It is also possible that under careful conditions of laying, lighter structures may be used with a saving in the cost of construction

Concrete culvert pipe in use on the Chicago and Illinois Western Railway: The pipes were built for use in low embankments where the top would be eighteen inches below the bottom of the ties and give satisfaction under heavy freight traffic.

The pipes were made in the shape of hollow cylinders with square ends, and they were four feet in length. They were molded with an interior of four feet with six-inch shells giving an outside diameter of five feet. The pipes were laid end to end in trenches cut as near to the shape of the pipes as possible and were covered with earth thoroughly tamped around the top and sides.

The concrete used in manufacturing these pipes was composed of American Portland cement, limestone screenings and crushed limestone that has passed through a ¾ inch diameter screen after everything that would pass through a ½ inch screen had been removed. The concrete was mixed in the proportions of one part cement to three and a half parts each of screenings and crushed stone. All except form work was done by common laborers. The pipes were left in the forms till the morning of the day after molding, the average time being sixteen hours.

(To be continued.)

ACCIDENTS IN AMERICAN COLLIERIES.

The United States Bureau of Mines has compiled statistics which show that during the calendar year 1912, 2,360 men were killed in and about the coal mines of the United States. Based on an output of 550,000,000 tons of coal produced by 750,000 men, the death-rate per 1,000 employed was 3.15 and the number of men killed for every 1,000,000 tons of coal mined was 4.29. The number of men killed was the least since 1900, the death-rate per 1,000 employed was the smallest since 1899, the death-rate per 1,000,000 tons of coal mined was tbe lowest, and the number of tons of coal produced in proportion to the number of men killed was the greatest on record. The following are the figures for the past few years:—

	Number Killed.			
Years.	Total.	Per 1,000 employed.	Per 1,000,000 short tons mined.	Production per death, short tons.
1907..........	3,197	4.88	6.93	144,000
1908..........	2,449	3.64	6.05	165,000
1909..........	2,668	4.00	5.79	173,000
1910..........	2,840	3.92	5.66	177,000
1911..........	2,719	3.73	5.48	183,000
1912..........	2,360	3.15	4.29	233,000

SEWAGE DISPOSAL BY DILUTION.

By Horace S. Griswold.*

The general principles of sewage disposal and informa-tion as to the various methods used have been discussed in *The Canadian Engineer* several times over, but the following extracts from a paper by Horace S. Griswold, of the University of California, on "Sewage Disposal by Dilution" with special reference to inland streams, will no doubt be of interest to all readers connected with work of that character. The general outline followed comprises seven heads:

1. Sources and Composition of Sewage.
2. Decomposition of Sewage.
3. Present Status of Sewage Disposal.
4. Sewage Disposal by Dilution.
5. Clarification of Sewage by Screening.
6. Sewage Effluent and the Diluting Stream.
7. Conclusions Based on California Conditions.

He goes on to say:—

Sewage is the used water supply of a community; composed ordinarily of the drainage from sinks, the discharge from water closets and baths of botels, apartments and residences; the wastes from bakeries, laundries, stables, saloons, butcher shops; together with rain water from roofs and washings from streets. In general appearance sewage resembles soapy, dirty, wash-bowl water, but with the addition of various floating matters such as pieces of paper, rags, matches, bits of vegetables, fecal matters and other waste materials.

The refuse from slaughter houses, discharges from hospitals and sanitariums, the wastes from breweries, tanneries or canning establishments may be added to the residential wastes. Sewage, then, contains all excreta of human life and excreta of industrial life of various forms.

In spite of the variety of objectionable materials of different sorts conveyed by water carriage, fresh sewage is comparatively inoffensive to sight and has only a slight odor. This is due to the extreme dilution in which these matters are carried. According to Messrs. Kinnicutt, Winslow and Pratt, the sewage from an average residential American city will contain only from two hundred to eight hundred parts of solid matters out of one million parts of sewage (0.2 to 0.8 of a gram per litre), or less than one-tenth of one per cent. This solid matter is half mineral and half organic, with about seventy five per cent. of the mineral and sixty per cent. of the animal and vegetable matters in solution.

Residential sewage is influenced in its character by the relative content of the bodily wastes. The character and composition of the bodily wastes depends upon the type of food the body is receiving as its fuel.

The body uses as its material for developing energy and repairing wastes a rather restricted list of substances known as food stuffs. These ordinarily include:

1 Water,
2 Inorganic salts,
3 Proteids and albuminoids,
4 Carbohydrates,
5 Fats.

Water and the inorganic salts are of no particular significance in the present discussion.

The proteid and albuminoid bodies, found in such foods as meats, cheese, eggs, gelatin, containing C, O, H and N as the basic elements, are extremely complex in character, but are rather readily broken down into simpler compounds.

* Instructor in Civil Engineering, University of California.

The carbohydrates are familiar in every day life in the various starches and sugars, and are relatively simple in structure. The fats, butter as an example, are among the less complex organic compounds, but are more stable, relatively, than either the nitrogenous or the carbohydrate group.

These substances are taken into the body, utilized by it through the processes of digestion and nutrition; and the waste products are given off in the sweat, the breath, the sputum, the urine and in the feces.

The feces are of importance as one of the main constituents of sewage and are composed primarily of:

1. Various indigestible materials, ligaments of meat and cellulose from vegetables.
2. Portions of various undigested materials, fragments of meats, fats, vegetables.
3. Certain products of intestinal secretions.
4. Products of intestinal bacterial decomposition.
5. Inorganic salts of various sorts.
6. Bacteria, harmless or pathogenic, in vast numbers.

The bacterial content per day in the feces of the normal adult has been determined as about thirty million million, and constitutes some thirty per cent. of the total weight in the dry solid matter of the feces.

When it is remembered that typhoid and dysentery are all too common; that the bowel discharges of a person suffering from these or other intestinal diseases may contain the specific germ in vast numbers, then the danger of sewage to the health of the community begins to be manifest.

Sewage, after being deposited in a sewer, does not long remain in its original condition; natural processes occur which completely transform its character. The process of change is commonly spoken of as decomposition.

2. Decomposition of Sewage.—In what follows, the term fermentation will be defined as "the action of micro-organisms upon carbohydrates." The term putrefaction will be defined as "the action of micro-organisms upon nitrogenous substances," i.e., proteids and albuminoids. Both fermentation and putrefaction are brought about by enzyme action. Decomposition will be defined as "the action of micro-organisms upon organic substances." Thus decomposition may mean fermentative action, or putrefactive action or both.

After many years of observation and study, it has been determined that the animal and vegetable constituents of sewage decompose from their original complex, unstable, organic form to a simple mineralized form. The final mineralized form closely resembles ordinary humus in appearance and composition. The change from the complex to the simple is brought about by a process of fermentation and putrefaction occurring in two related phases. The first phase is accomplished by the enzyme action of those sewage bacteria that live and multiply without air. The second phase is affected by sewage bacteria requiring oxygen. The two phases are not entirely separate and distinct; under certain conditions it is possible to have both anaerobic and aerobic decomposition occurring simultaneously.

The process of decomposition consists of the hydrolyzing and liquifaction of some of the simple compounds; a breaking down in structure of the more complex ones to those of less complexity, and finally, the complete oxidation and nitrification of these relatively simple substances. Gases of a more or less objectionable character, CO_2, CH_4, H, N, NH_3, H_2S, are liable to be among the products of these decomposition steps.

3. Present Status of Sewage Disposal.—Since the very earliest times it has been the effort of man to rid himself of the waste products of his life with the least trouble and danger. The method has progressed and developed from its original simple personal state, through the various processes of disposal by means of trench, midden heap, privy and dry earth closet, to the present almost universal system of water carriage. This system is used by the community, for the benefit of the community and is under community control. The water conveying and disposal of the wastes of life has been found so convenient and simple that for years, with no thought of danger, communities discharged their crude sewage into the nearest watercourse. Conditions of positive physical nuisance, brought about by an overloading of the streams, finally forced a restriction on and a governing of the method.

For many years the opinion was held that sewage, in almost any quantity, might be safely placed in a stream, as the flowing water would purify itself. To-day, however, it is known that flowing water is dangerous in so far as it rapidly conveys polution from distributor to consumer. The greater the lapse of time between the deposit of pollution in a water supply and the drinking of that water, the better for the consumer.

In spite of the fact that there is a self purification of water through natural agencies, sanitarians of to-day discountenance the unfiltered use of an inland stream for water supply purposes.

The self purification of a stream may be satisfactory as regards the removal of nuisance, but there is no surety as to the bacterial purification at all times. There are many natural probable sources of pollution of these waters, so that sewage clarification to the extent of preventing nuisances should ordinarily be sufficient for sewage effluents entering most inland streams.

The placing of crude or clarified sewage in any body of water as a method of disposal, is spoken of as disposal by dilution.

4. Sewage Disposal by Dilution.—There are three general conditions governing the disposal of sewage by dilution:

1. Disposal by dilution in inland streams.
2. Disposal by dilution in lakes.
3. Disposal by dilution in tidal waters.

When disposing of sewage by dilution in inland streams, particular care must be observed with regard to the following:

1. The diluting body should show no floating matters which are offensive or which might strand on the banks of the stream.

2. A sufficient portion of the settling matters of the sewage should be removed to prevent the formation of mud banks; care should be taken to insure a proper relationship between the velocity of the stream and the size of the materials admitted to it.

3. The relation between the volumes of sewage and the diluting water should be such as to insure an aerobic decomposition of the sewage. It is also desirable to insure a residual oxygen content in the stream sufficient to maintain the major forms of fish life.

4. The question of a sewage containing a large amount of trade wastes will require a particular study for each case.

The removal of floating bodies which are objectionable or which might strand is very readily accomplished in any of the clarification processes:

1. Screening.
2. Sedimentation.
3. Chemical precipitation.
4. Septic tank process, either of the Cameron or the Imhoff type.
5. Single contact beds.

It should be distinctly noted that these processes are

simply methods of clarification, the sewage effluent from them is highly organic and unstable and must acquire from some outside source sufficient oxygen to complete the process of decomposition to a condition of stability.

Of the clarification processes noted, perhaps the most simple under favorable conditions is that of screening.

5. Clarification of Sewage by Screening.—The use of screens for the removal of settling and suspended matters has been extensively followed in Europe for some years and to-day we are employing them more and more, as the opportunity offers, as a method of clarification. Screens may be classed as coarse or fine. The first type consists of gratings or bars; the second are generally constructed as a net mesh.

Coarse screens are used to remove all gross refuse matter which might be objectionable. When sewage is pumped, screens are installed to protect the pumps. Such screens are generally limited to minimum clear openings of about one-half inch. In design they may be either of the fixed or movable type. The fixed screen may be of bars, iron or wood, set upright or horizontally. The fixed grillage is hand cleaned with a rake whose teeth fit the clear spaces. The upright screens are best set at a slight inclination, generally with the direction of flow. The movable grating may consist of:

1. Fixed rods with movable scrapers.
2. Movable rods with fixed scrapers.
3. Movable screens with fixed scrapers.
4. Movable screens with movable scrapers.

Screening devices require constant attention to prevent severe clogging and resultant backing up of the sewage, and should in general be installed in duplicate to admit of continuous operation.

The amount of screenings removed per million gallons of sewage clarified will vary greatly, depending entirely upon local conditions. So also will the cost of removing the screenings. Foreign practice appears to allow from ten to thirty square feet of screen per million gallons of sewage treated per day.

Fine screens or sieves deal primarily with the settling and the suspended organic matters. These screens are either fixed or movable and, to operate successfully, care must be taken:

1. That the screenings do not disintegrate on the screen
2. That no deposits are formed in the screen channel by the blocking of the screen and the backing up of the sewage.
3. That the screens be easily adapted to variations in flow.
4. That continuous operation be insured by easy interchange of screens or duplication of installation.

Various endless belts with different kinds of scrapers have been developed and have filled the particular needs in a satisfactory manner. These fine screens have a minimum mesh clearance of about one-thirteenth of an inch. General practice allows from ten to fifty square feet of screen per million gallons of flow.

Perhaps the most well-known fine screen developed in the country is the Weand Segregator. The original unit is installed at Reading, Pa., and has a capacity of eight million gallons' flow per day. This rotating screen consists of an iron and steel horizontal cylindrical frame, six feet in diameter and twelve feet long, upon which is placed forty mesh Monell metal wire cloth, protected by a five-eighths inch mesh copper screen.

The sewage enters at one end of the cylinder on a line with the horizontal axis, flows over a spreading plate and drops upon the screen. The water of the sewage passes through the cloth, while the solids are carried upward by the rotating screen till opposite a series of oscillating jets outside of the cylinder, which force them from the cloth. The screenings fall to the bottom of the cylinder and are carried by a worm conveyor to a point of storage.

This screen removes from thirty to thirty-five cubic feet of wet matter per million gallons of sewage screened. The screenings contain about ninety per cent. of moisture.

A screening installation of any type must accomplish certain definite results. The particular governing conditions will depend largely upon the relation between the sewage flow and the diluting stream.

6. Sewage Effluent and Diluting Stream.—All surface waters in their unpolluted state contain atmospheric oxygen to a greater or less extent, depending on such factors as temperature, atmospheric pressure, kind and quantity of aquatic life. When clarified sewage effluents are placed in these waters, this dissolved oxygen is utilized by the organic matters of the effluent to complete the process of decomposition. The relation between the volumes of effluent and diluting water should be such as to supply all the oxygen needed by the suspended and dissolved organic matters of the sewage. In addition thereto there should be unconsumed a residual oxygen content of from thirty to fifty per cent. of complete saturation, at the particular temperature and pressure.

When either crude or clarified sewage is placed in a stream in such quantity that it completely exhausts the oxygen content of the water, then the normal aerobic decomposition ceases. The unobjectionable process becomes a most obnoxious anaerobic one, with no final condition of stability.

This has been the experience of many cities in this country and of the larger cities of Europe which continued to discharge sewage into a stream without regard to the capacity of that stream to decompose sewage. The changing of the Thames into an immense cesspool was experienced by London during the summers of 1858-59, and has been most vividly described by Budd in his monograph on typhoid fever. "Stench so foul, we may well believe, had never before ascended to pollute this lower air. Never before, at least, had a stink risen to the height of an historic event. Even ancient fable failed to furnish figures adequate to convey a conception of this thrice Augean foulness. For many weeks the atmosphere of Parliamentary Committee Rooms was only rendered barely tolerable by the suspension before every window of blinds saturated with chloride of lime, and by the lavish use of this and other disinfectants. More than once, in spite of similar precautions, the law courts were suddenly broken up by an insupportable invasion of the noxious vapor. The river steamers lost their accustomed traffic, and travellers, pressed for time, often made a circuit of many miles rather than cross one of the city bridges."

The experience in the past of many American cities has led to the conclusion that a minimum flow of from 4 to 7 cubic feet per second per 1,000 of population sewering into a stream is necessary to prevent the formation of a nuisance; providing the stream has sufficient velocity to prevent the formation of sewage mud banks. Roughly, it has been found that a stream will purify one-fiftieth of its volume of sewage but not one-twentieth.

It is not possible to set definite limits as to the amount of sewage containing trade wastes, that may be cared for by a stream. Biological and chemical factors have to be very carefully considered. Wastes containing objectionable foreign particles, acids, or alkali, or other materials poisonous to the life in a stream create entirely different conditions from

those obtaining when domestic sewage alone is discharged into a stream.

7. Summary and Conclusions.—Sewage is a mixture of highly complex organic substances and, under certain conditions, will form offensive decomposition products. Sewage may contain pathogenic organisms in large numbers.

A satisfactory disposal by dilution, whether preceded or not by a clarification process, is only to be had in streams possessing a satisfactory diluting volume. Streams having a large variation between maximum and minimum flow conditions, are particularly liable to give rise to nuisances.

Satisfactory disposal by dilution implies the avoidance of physical nuisance; it does not imply a satisfactory bacterial removal.

The streams of California, with the possible exception of the Sacramento and the San Joaquin, do not exhibit sufficient dry weather flow to receive the clarified sewage of communities, and so dilute it as to avoid nuisance.

All questions of legality waived, it would seem that natural stream conditions in California preclude the consideration of sewage disposal without purification.

This conclusion is based on the impossibility of avoidance of stream nuisance.

HYDRAULIC DREDGE "PORT NELSON."

The 24-inch hydraulic dredge "Port Nelson," built by the Polson Iron Works Toronto, for the Department of Railways and Canals, was successfully launched on Saturday, May 31st, five weeks after the material was ordered, which constitutes a record in the history of Canadian shipbuilding. It was christened by Mrs. Hearst, wife of Hon. W. H. Hearst, Minister of Lands, Forests and Mines in Ontario. The contract for the dredge, which amounted to $270,000, was placed by the government in the beginning of April and the company expect to deliver the dredge in Montreal before the expiry of the contract time. It was designed by Wm. Newman, M.I.N.A., and following is a description of the dredge: The dimensions of the hull are as follows:—

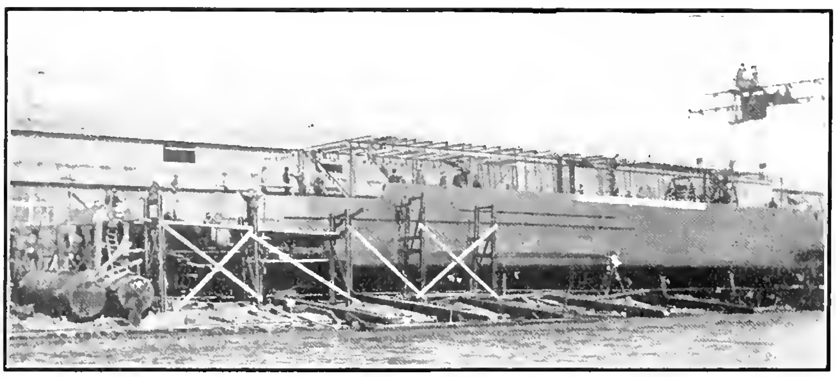


Fig. 1.—Showing the "Port Nelson" on the Ways.

Length	180 ft.
Beam over all	44 ft.
Depth at side	11 ft.
Draft, about	6 ft.

The dredge is to be of scow model with a spoon bow, as shown on drawings, and is to have circular bilges with 18-inch radius. All material and scantlings are designed up to, and in most cases above, Lloyds' requirements.

As the dredge will be towed around the Labrador coast to her destination, which is Port Nelson, and for which the government are now calling for tenders, her design and structure throughout are being made amply strong to enable her to take this trip with safety, the shell plates being ½ inch throughout, and keel plates ⅝ inch. The sheer plate extends 3 feet above the main deck and is surmounted by heavy steel bulwark rails, these lending additional longitudinal strength to the structure.

The deck stringers are ⅝ inch thick, and the deck itself is ¼ inch chequered plate. The deck housing is of steel structure of ¼ inch plate, and will be divided into three parts by two longitudinal watertight bulkheads. The framing is exceptionally heavy, with 10-inch channel floors weighing about 25 pounds to the foot, and located 20 inches apart. The side frames and deck beams are all 6-inch 15-pound shipbuilding sections. The longitudinal girders used are of 15-inch channel, 35 pounds to the foot, and the longitudinal truss frames are of 12-inch 25-pound channels.

There are two 26-foot metallic life boats and two life rafts.

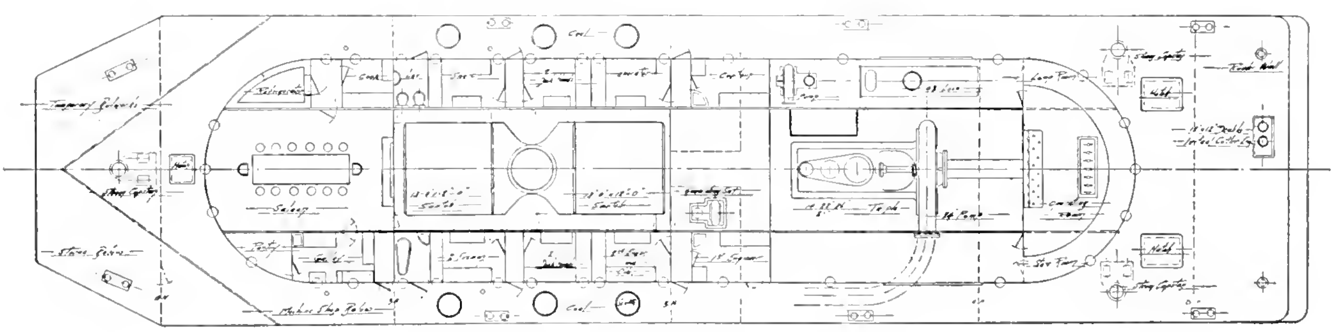

Fig. 2.—Showing Plan of the "Port Nelson."

The dredge will be equipped with a complete electric light outfit and search lights. A complete machine shop outfit consisting of air compressor, planer, lathe, drills, etc., will be installed so that the dredge will contain the necessary outfit for effecting any repairs required from time to time.

It will have a discharge pipe of 24 inches in diameter, and the hull will be divided into six water compartments by five transverse bulkheads.

The main engine for driving the pump is of the marine triple expansion type; cylinders 14 inches and 22 inches and 36 inches in diameter by 21-inch stroke. There are two Scotch boilers 13 feet in diameter by 12 feet long. In addition to these there is an auxiliary boiler of the locomotive marine type situated on deck, being 48 inches in diameter by 14 feet long, and alongside of this is an 8-inch wrecking pump.

The dredge will be equipped throughout for salt water service, with surface condenser and copper piping. The circulating water will be supplied by an 8-inch centrifugal pump driven by a 6 x 7-inch vertical engine. The air pump is of the vertical simplex beam type. It will also be equipped with feed and bilge pumps. For the purpose of raising and lowering the suction pipe, a 12-inch by 12-inch, two-cylinder double-acting engine will be provided on the main deck forward. There will also be three capstans provided, operated by 6-inch by 8-inch double-acting engines. The boom for raising and lowering the suction pipe is located at the suction end of the dredge, is 64 feet in length, and is built up of steel shapes and plates throughout.

The cutter engine consists of 12 x 12-inch two-cylinder doublt-acting horizontal engine. The cutter head is 5 feet in diameter, with a spare cutter head 4 feet in diameter.

A general fire service pump, hand deck pump, and necessary hose to reach all over the ship will be furnished with the dredge.

The gallery, dining room, cabin and crew's quarters will be fitted up and furnished complete. The dredge will also be supplied with 3,000 feet of piping and pontoon for the discharge. It will commence operations at Port Nelson this summer, where a harbor thirty feet deep at low tide will be dredged, thus giving Canada her first ocean port of any importance on Hudson Bay. Some $4,000,000 has been appropriated by the government for this year's work, which will be supervised by Mr. H. T. Hazen, engineer for the Department of Public Works.

STANDARD OF ABRASION FOR PAVING BRICK.

The organizations of city officials interested in standardizing paving specifications adopted a standard rattler for making abrasion tests and standard methods of making the tests but did not see fit to specify the maximum allowable amount of abrasion until a year or so ago. After two or three trials the specification has been set at 22 per cent. with proviso in the specifications of the American Society of Municipal Improvements that "where medium or light traffic or other conditions exist which, in the opinion of the engineer, do not require a brick capable of giving an abrasion loss of only 22 per cent., brick of a quality which will give a loss of 25 per cent. or even 28 per cent. may be used.

SPECIAL LIBRARIES' ASSOCIATION.

The fifth annual meeting of the association will be held at the Hotel Kaaterskill, Catskill Mountains, New York, June 24th to 26th, 1913.

Information regarding hotel arrangements can be had from Harrison S. Downs, 19 to 21 West 44th Street, New York City. Travel information can be had from F. W. Faxon, chairman, Travel Committee, 83 Francis Street, Boston. An attractive post conference trip will be arranged by the travel committee in the Lake Champlain district.

COAST TO COAST.

Vancouver, B.C.—Timber as an asset of provincial wealth is daily becoming of greater value. With the opening of the Panama Canal and the free entrance of lumber into the United States, British Columbia timber will, it is predicted, be more sought after than ever. "The day of $2 timber is long past." was the answer of Mr. R. C. Bidlake, of the Snowdon-Bidlake Logging Company, of this city, when asked concerning the value of standing timber. "Values are advancing rapidly, and it is impossible to-day to buy at anything like the figures of a year or two ago. For good timber that can be taken out at a reasonable cost, say, on Crown grants, it is very doubtful if anything can be bought under $2.50 a thousand feet, taking the general run of the cruise, and figures over that are happening every day. Only a week or so ago a tract of one hundred million feet on Menzies Bay, Vancouver Island, was sold for $3 per thousand feet, and another recent purchase of a tract a little smaller also went at $3. Then there was the purchase on the Lower Lillooet a few weeks ago, also quoted at $3. Crown-granted timber is in strong demand, and very few small tracts can be had for less than $3. That it is being paid shows that the timber is worth it. Besides, at that figure buys are good, since values are advancing. A factor in determining values also is whether the logs have to be towed down the coast, for losses are bound to occur."

Edmonton, Alta.—The city council has authorized the commissioners to spend $125,000 upon further provision for the sedimentation and filtration of water at the present pumping station. This sum is to be used in the construction of a 5,000,000 gallon sedimentation basin and filter units with a total capacity of not less than 4,000,000 gallons, together with a clear water basin to take care of the same. In this connection the commissioners reported as follows: "We feel that this is not making too great a provision to take care of the water in the interval between now and the time that the new waterworks scheme might be ready for operation. If this amount is authorized, work can be proceeded with very shortly with the construction of a sedimentation basin, and tenders received for the construction of the filters and the clear water basins. We estimate that the sedimentation basin will cost in the neighborhood of $50,000; filters and clear water basin, $64,000, the housing, pipes and incidentals to make up the balance. Judging from the increase of population during the past year, and taking the same percentage of increase for another four years, our population will then be in the neighborhood of 120,000, and the provisions made are not too ample to take care of, and give satisfactory service for, the intervening years." A motion was made and adopted that the report be accepted, that the commissioners be instructed to proceed with the work specified this year in order that the filters may be in operation by next spring, and that the city solicitor bring down the necessary by-law covering the expenditure. If good progress is made upon the work there should be no more muddy water at the time of the spring freshets, which will become forever a matter of painful memory—the muddy water, not the freshets.

Montreal, Que.—Mr. Norman M. McLeod, contractor in charge of Montreal's big filtration plant, to cost about three million dollars, has sent a notarial protest to the city, saying that the structural design is unfitted for the bearing power of the soil, as proved by the subsidence of certain work. He says that he will do the repairing to the cement work damaged by frost. but he wishes to be relieved of all responsibility for the failure. The protest recites the history

of the contract and the notice received on April 3 to make good damage to cement, which was attributed to frost. Mr. McLeod says also that on May 12, the city protested to him to go on with and make good the work said to have been damaged by frost, and repudiating his charges of defective foundations. The following serious errors in the design of the structure are named by Mr. McLeod: 1. In regard to the original irregularity of the surface of the ground, which necessitated lowering high places and filling in low ones, thus offering unequal bearing capacity for the foundations, the structure should have been designed to provide for footings of proportionate bearing capacity to prevent unequal settlement. 2. That the structural features of the building should have been designed to be separate and distinct from those features dictated particularly by the object for which the building is to be used, the footings and piers being carried down to a firm foundation separate or otherwise, supported with due regard to the nature of the material on which the structure is to be founded and independent of the floor. 3. The construction and design of the arch system is such as to have aggravated any damage or disturbance beyond what would ordinarily occur. 4. The floors and walls should have been designed to be absolutely watertight in view of the fact that even so small an amount of leakage as that allowed by the specifications into soil of the nature in question will undoubtedly cause settlement or subsidence, which must result in the cracking of the floor walls and the certain failure of the structure.

Ottawa, Ont.—At the sittings of the Board of Railway Commissioners to be held in Ottawa on Tuesday, June 17th next, the board will take into consideration the proposition that, by limiting the height of freight cars operated on railways subject to its jurisdiction to 13 feet 6 inches from the top of rail to the running board, trainmen would be safeguarded, and grade separation facilitated; also of the proposals submitted by the Canadian Freight Association in conformity with the suggestion that this object would be promoted by basing the minimum weights of the Canadian freight classification for light and bulky articles on the cubical capacity of box cars, instead of on their length, as at present.

Ottawa, Ont.—The Government has decided to institute a new departure in connection with the forestry branch which will undertake the work of investigating the possibilities of conserving our forests by reducing waste in manufacture, by prolonging the life of forest products used in construction, and developing uses for products now wasted for the lack of knowledge as to how they may be employed. To take charge of this work Hon. W. J. Roche, Minister of Interior, has selected A. G. MacIntyre, at present editor of the "Pulp and Paper Magazine," and acting secretary of the Pulp and Paper Association. Mr. MacIntyre is a graduate of Acadia University, and he also graduated from McGill University in chemical engineering. He was chemical engineer of the Jonquiere Pulp Company, where he had charge of the water power, water discharge measurements, etc., and he put in a bleaching system of his own design, saving in the value of the paper. He was also engineer in charge of construction for Price Bros. at Kenagami, Que., and did the investigation for the new sulphite mill. His special qualifications should assure the successful carrying out of the project. The work will be carried on at present in co-operation with McGill University. The various classes of investigation to be carried out will be as follows: Wood tests, timber physics, wood preservation, wood distillation, and wood pulp. This is an advanced step on the part of the Department of the Interior The forestry branch is one in which Dr. Roche has been particularly interested, and this new step is along the lines of modern scientific forestry work in Germany and other European countries. To fulfil the prime object of forestry, which is to preserve and conserve our forests, it is felt this line of development must be undertaken.

Calgary, Alta.—That it will be inadvisable to establish a filtration plant on a large scale until Calgary definitely settles the question of source of water supply is the emphatic statement of Waterworks Engineer A. Ellison Fawkes. Mr. Fawkes discussed the situation at some length after having consulted Saturday with T. Aird Murray, of Toronto, one of the recognized authorities on water supply in America. At the present time Mr Fawkes is having erected a temporary chemical purification plant which will be part of the pumping station supplying water from the Bow River as a standby to the Elbow River gravity system. This pump will afford a 20,000,000 gallon supply daily from the Bow River, and the water will be treated with hypochloride and sulphate of aluminum. At the present time, the water taken from the Bow is treated only with hypochloride, which effectually kills all germicidal life. The addition of aluminum sulphate to the water, however, will also remove suspended matter and the chemical precipitates, giving a clarity of about 75 per cent. The hypochloride makes the water practically pure so far as typhoid and the like are concerned, having an efficiency of about 98 per cent. The by-law carried an appropriation for $50,000 for the establishment of a turbidity filtration system in connection with the Bow pumping station, but Mr. Fawkes decided that it would be impossible to erect a proper filtration system at this point under a cost of $400,000. To spend such a sum on a filtration plant when the city is as yet undecided whether the supply shall ultimately be obtained by gravity from mountain streams or lake in the Rocky Mountains, the waterworks engineer considers foolish. He discussed these points with Mr. Murray when that expert looked over the water situation here, and Mr. Murray agreed that the temporary chemical treatment of the water is the best solution of the problem at present. It costs less than $500 to install the chemical treating apparatus at the Bow River station, and it will soon be in working order. According to Mr. Fawkes, the aluminum sulphate not only removes suspended particles from the water, but also removes the chemicals after their work is done. When added to the water, the aluminum sulphate spreads out in a glutinous form and collects the infinitesimal particles of suspended matter, the dead germicidal matter which has been killed by the hypo-sulphide, and also the precipitate formed by the hydro-sulphide after the chemical reaction takes the addition of the aluminum sulphate and is then strained out through a series of screens. The water comes out 98 per cent. pure, so far as germ life is concerned, and 75 per cent. clear of suspended matter as silt, clay and the like.

Port Coquitlam, B.C.—Engineers for the cities and municipalities on the route of the proposed highway to Port Coquitlam have begun preliminary surveys of the grades with a view of estimating the cost. It is probable that a new road will be built between the North road and Port Moody on an easier grade than that of the present highway. The engineers forming the party were: City Engineer Fellowes, Vancouver; Engineer McPherson, Burnaby; Col. Davis, Port Moody; Engineer Kilmer, Port Coquitlam. In addition to the new road from the North road to Port Moody, City Engineer Fellowes believes that there ought to be a new route from the Vancouver city boundary to Barnet to eliminate some of the heavy grades on Hastings Street. He also advocates that Pender Street be made the main route out of the city because of Hastings Street being a car line thoroughfare. Profiles will be drawn of the various sections and another meeting will be held later. The plan will then

be laid before the Provincial Government with a request for financial assistance.

Vancouver, B.C.—Encouraging reports of the manner in which the interior of the province in the Hope district is filling with ranchers are brought back to the city by Mr. George D. McKay, provincial timber inspector, who returned to this city recently after a visit of inspection of the forest fire protection service. "It is four years since my last visit to the district, and I was amazed at the great alteration," said Mr. McKay. "All along the route of the new Pacific Highway the land is occupied with ranches, and the country looks prosperous. The Pacific Highway is going to be a wonderful thing to enable our residents to see the scenic beauties of the province, and will attract thousands of wealthy automobilists here, too," said Mr. McKay. "The roadway is being cut through a hundred-mile stretch of the most wonderful scenery imaginable. It is twenty-four feet wide all the way, and will start from Chilliwack and run clear through to Hope, and thence on to Silver Creek and the summit of the Cascades, striking the old Dewdney and Similkameen trails to Nicola and the Boundary country. There are wonderful views of mountain and valley scenery, nearly the whole way. It will be one of the great resorts for automobilists who want to see Nature at her grandest." Superintendent Sutherland and his staff of 100 men have already got sixteen miles of road in the Yale district completed, and are following up the work as fast as the snow disappears in their path. Mr. McKay does not anticipate any danger from floods in the Chilliwack district unless the thaw from the mountains should be delayed, and a heavy drainage comes down toward the middle of June, when a high tide is due. The tide from the ocean backs up the waters of the Fraser River as far as Sumas, and the danger to be feared is that the high tide should come at a time when the river is swollen with the mountain thaws.

PERSONAL.

MR. DOUGLAS SPENCER, of London, England, arrived in Toronto this week. Mr. Spencer's visit is a strictly business one. While here he is making his headquarters with the Canadian Boving Company of this city.

MR. GEORGE IRVINE has been appointed Canadian manager for the National Meter Company, of New York. Mr. Irvine will make his headquarters at 229 Spence Street, Winnipeg. He is a Canadian by birth and fully familiar with conditions existing in Canada. He has been in the employ of the National Meter Company for nearly twenty years, and has had long practical experience in connection with waterworks matters.

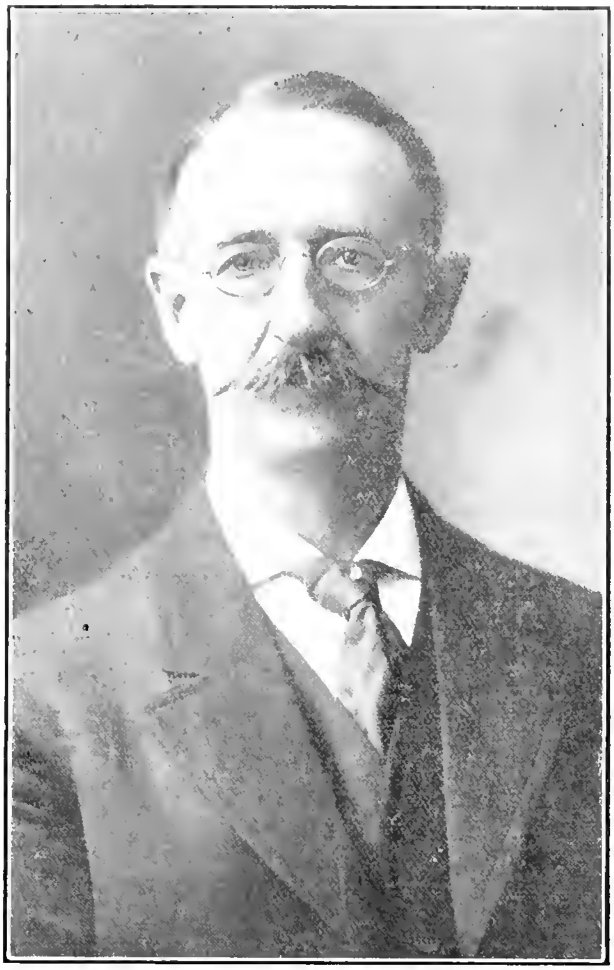
MR. SAMUEL HILL, president of the American Road Builders' Association, at the invitation of President George McAneny, of the Borough of Manhattan, and President Cyrns C. Miller, of the Borough of the Bronx, New York City, on May 26th delivered an illustrated address on the subject "The Highways of the Northwest" at the residence of President McAneny, before an assemblage of over fifty municipal engineers who are in charge of the highways of Greater New York.

OBITUARY.

MR. J. K. McLEAN, Dominion Land Surveyor at the Sarcee Reserve, near Calgary, died on May 23. Deceased was the eldest son of the late Donald McLean, formerly collector of inland revenue in Guelph. He was a resident of Ottawa.

THE PRESIDENT OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

It gives us great pleasure this week to be able to present to the readers of *The Canadian Engineer*, a portrait, together with some facts relating to the career of Professor George F. Swain, President of the American Society of Civil Engineers, which society is to hold its summer meeting in the city of Ottawa this month. Owing to the fact that many of our readers are members of both the Canadian and American societies, we feel they will be interested in learning something about the career of Professor Swain.



Prof. Geo. F. Swain.

George Filmore Swain was born 2nd of March, 1857 in San Francisco. His father was a prominent citizen of that city and a leading merchant. It was while he served as president of the Chamber of Commerce, that he was appointed superintendent of the branch mint during the Presidency of Abraham Lincoln. Swain, Jr., received his preparation for college at a military school. When sixteen years of age he became a student at the Massachusetts Institute of Technology. His teacher in civil engineering was Professor John B. Henck. In 1871 Mr. Swain received the degree of Bachelor of Science. This was followed by courses of study in Berlin, Germany, where he specialized in bridges, railroads and hydraulics. He returned to the United States in 1880, and shortly after was appointed instructor in civil engineering at the Massachusetts Institute of Technology. He was soon promoted to the position of assistant professor, and a few years later, in 1881, became full professor in charge of

the department of civil engineering. In 1909 Professor Swain was offered and accepted the Gordon McKay professorship of civil engineering in the graduate school of applied science, Harvard University. In 1893 upon the organization of the Society for Promotion of Engineering Education, he was appointed the second president of that society. His publications include Notes on Hydraulics and also on Structures, for the use of his classes. In 1887 he contributed a paper to the American Society of Civil Engineers on the "Calculation of Stresses in Bridges for Concentrated Loads," which paper has had a very marked effect upon present practice so far as structural computations and investigations are concerned. Professor Swain has served on a number of different commissions, among them being the Boston Transit Commission organized for the construction of the Boston Subways; the commission appointed to fix the method of eliminating grade crossings in various parts of New England, and has in very many cases been called as an expert in court cases, not only in Massachusetts but elsewhere.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE CANADIAN FORESTRY ASSOCIATION.—National Convention will be held in Winnipeg, Man., July 7-9. James Lawler, Secretary, Canadian Forestry Association, Canadian Building, Ottawa.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memorial Museum, Ottawa.

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held at Chicago, Ill., Feb. 16-20, 1914. Secretary, E. E. Kraus, Harrison Bld., Philadelphia, Pa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—176 Mansfield Avenue, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, A. B. Lambe, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, E. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 534 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSIOCATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Edmund Burke; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Bedford McNeill; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. H. W. Claudet, J. B. Porter, H. E. T. Haultain and W. N. Miller and Messrs. S. S. Fowler, R. W. Leonard and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Pingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

TECHNOLOGY CLUB OF LOWER CANADA.—President, F. E. Came; Secretary-Treasurer, E. B. Evans. Meets twice yearly.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

DESIGN OF A STRUCTURAL STEEL PLANT

THE HANDLING OF EQUIPMENT AND MATERIAL—LIGHTING AND POWER FACILITIES—COMPRESSED AIR AS A POWER TRANSMITTER—WATER SUPPLY AND DRAINAGE

By E. H. DARLING, M.E.*

(Continued from last issue, page 818.)

HANDLING Machinery and Industrial Tracks.—Next to the selecting of the machinery there is no one feature about a structural steel plant that should receive more careful consideration than the handling equipment. The cost of handling is the largest item in the labor account, and the capacity of the plant depends a great deal on the speed with which material is fed to and taken away from the various machines. Even after every unnecessary motion is eliminated, there is a great deal of handling to do to each piece and the weight, length and flexibility of most of them call for care and special appliances.

In the ordinary run of work it is seldom that a piece of material from the steel mills will exceed three tons in weight. The stock yard crane, however, should have at least ten tons capacity as it is usually desirable to lift several pieces at one draft. Only one crane, having a ninety-foot span, travelling the full width of the lot, will be needed at first. At some future time another crane and runway may be added, which will not only increase the handling capacity, but will double the area of the stock yard.

This yard crane will unload material from the cars and sort it. As it is required in the shop, it will be put on small trucks which run on narrow-gauge tracks from one end of the shop to the other. Inside the building the hoists on the bottom chords of the trusses afford a means by which the material may be taken off the trucks and transferred to any point across the shop. At each end of the building, however, on account of the great deal of handling that takes place, at these points, it is advisable to have travelling cranes of about sixty-foot span—a 10-ton crane at the stock yard end and a 15-ton crane at the shipping end. These cranes will also be found of great service in transferring material from one aisle to another.

At the punches, longitudinal trolley beams with trolleys and chain hoists are necessary to hold the work as it is fed through the machine. These trolley beams must be suspended below the trusses and have openings for the trolleys on the trusses to pass through. Special travellers and jib cranes can be arranged to suit the need of any particular machine.

In that part of the girder shop where the girders are assembled and handled, it will be necessary to have two travelling cranes of thirty-ton capacity. Travelling jib cranes for carrying riveting machines can be arranged to run along the east side underneath the over-head cranes. In the structural shop the riveters will have 3-ton travelling cranes with fifteen-foot span carried on runways suspended from the roof trusses.

Three- and five-ton air hoists will be required wherever much lifting is to be done, provided the head room is sufficient for the hoist. For holding work at machines, however, a chain block is better, as air hoists are not steady enough. Wherever possible, material will be laid on horses or skids, so as to save raising and lowering more than necessary. If much of it has to be done at any point, rapid-acting blocks should be used

In course of time it will be found convenient to have a thirty-ton travelling crane with seventy-five-foot span in the yard at the north end of the plant. Under it finished material may be stored and loaded for shipment as required. It can be used for assembling large trusses when it is necessary to put them together at the works before shipping.

All the thirty-ton cranes should have 5-ton auxiliary hoists, or should be provided with change gears, as some cranes are now made. This will save a great deal of time when the crane is used for handling light pieces, the slow motion or main hoist being used only for heavy loads.

The handling equipment under certain conditions should include a 10-ton locomotive crane. Such a machine will be found of great service during construction for unloading and placing building materials, machinery, etc. It will also be a great convenience, if not a necessity, in moving cars, unless unusually good shunting service is available from the railway company. It may be used to good advantage by the erection department for certain work.

All parts of the handling equipment should have a wide margin of strength. Chains, hooks, cables, chain blocks, etc., that are frequently overloaded, soon give trouble and become dangerous. The most serious accidents of a structural steel shop are the result of falling material.

Power and Lighting Systems.—Electric power is usually delivered as two- or three-phase alternating current at a high voltage, to be transformed to suit the requirements of the purchaser. For distribution about the plant a voltage of 220 or 500 volts is usually used. The higher voltage requires less copper in the feeders, but for a structural shop the lower voltage, i.e., 220 volts, is preferable. The presence of so much metal, the rough treatment which wires and conduits are liable to receive, makes it unwise to use a voltage that might be dangerous to workmen.

* McPhie, Kelly & Darling, architects and engineers, Hamilton, Ont.

The power equipment must include a motor-generator set, as direct current will be required for variable speed motors, such as cranes, reamers, etc. The motor side of this set should be of the synchronous type with sufficient capacity to correct the power factor of the plant. On account of the varying loads on the motors, the power factor is sure to be very low. The capacity of the generator should be well able to take care of the needs of the plant, including the lighting system and the extra travelling cranes which might be added in a year or two. A set with a capacity of 100 kilowatts direct current and a synchronous motor of 125 k.v.a. should give satisfaction.

The high voltage current will be brought down the tower at the end of the power house to the transformers, and from thence the low voltage current will be taken in conduits to the bus-bars of the switchboard. A separate switchboard will be needed for the direct current system. From the switchboards feeders in conduit will run to the machines in the power house and template shops. For the main shop the feeders will pass up the tower and over head to cross-arms on the trusses of the building. A separate system, each on its own switch, should be provided for the different departments, so that any one can be cut out without interrupting the others. There should be three sets of A.C. feeders, one for each aisle of the shop, with room on the cross-arms for the additional aisles to be added later. There should be two pairs of D.C. feeders, one for the north cranes and one for the south cranes. If separate switches are provided at convenient points for cutting out each crane, it will hardly be necessary to have separate feeders for the other D.C. machines in the shop. There will only be one or two of these machines other than the reamers.

All wires above the bottom chord of the trusses will be carried on cross-arms bolted to the steel work, but wires below this level must be put in metal conduits. The starting switches for each machine should be as near the machine as possible. For the portable reamers a series of outlets must be provided on the columns about every forty feet down the shop so that the reamers can be connected up by means of a plug and a flexible chord wherever needed. Each outlet and, in fact, every branch circuit, must have a separate cut-out. In this and in all other particulars the rules of the fire underwriters must be followed, and every precaution taken to prevent short circuits and injury to the workmen.

For general illumination modern D.C. flaming arc 110-volt lights give as suitable and as economical a light as any. One light in every other bay arranged alternately on the right and left-hand side of the centre of each aisle will be sufficient for general illumination, while they may be spaced closer over the laying-out skids and the assemblers. As the power circuit is 220 volts, it will be necessary to connect two lights in series. Each pair must have a cut-out and every four lights should be controlled by a two-pole switch.

Sixteen-candle-power incandescent lights must be provided for each machine. These must be on good lamp chord and protected by wire cages having wooden handles. The power for these lights may be obtained by tapping the circuit that supplies the machine.

For the template shop the best illumination can be obtained by means of 100-watt tungsten lights suspended from the roof, three in each twenty-foot bay. Along the walls, over tables, or near machines, 16-candle-power carbon lights on drop chords will be used to give special illumination where needed.

Compressed Air Systems.—The transmission of power by means of compressed air is a very expensive method, but it is so convenient to handle, and can be adapted to so many uses, that it would be impossible to get along without it. A pressure of 90 to 100 lbs. per square inch is usually used for operating pneumatic riveters, hammers, reamers and hoists. The plant can easily be supplied by a 700-foot-per-minute, two-stage compressor. When the demand gets beyond this, it will be advisable to add a 1,400-foot machine to the equipment and the piping, etc., should be installed at the outset with this object in view. By having two machines of different capacity, the varying demand for air can be supplied a great deal more economically than by one large compressor.

The compressor will be belt-driven by a 125-h.p. induction motor. It should have an automatic throttling device which will cut off the supply of free air completely when the pressure in the system reaches its maximum. Such a governor can be adjusted to regulate the pressure within three pounds. This small variation need not be considered, as the method is much more economical in power than if a regulator were used which would permit just enough air in the intake to maintain the pressure constant. It causes great fluxations in the power used, however, as the compressor runs light when the intake is cut off.

In order to keep the pressure in the distribution system as constant as possible, and to relieve it of shocks, it is necessary to have a storage tank near the compressor. This tank will also act as a cooler, and in it will collect a great deal of the moisture that would otherwise pass into the distribution pipes. A large second-hand fire-tube boiler can be converted into a splendid storage tank. It should be set in a vertical position so as to allow a natural circulation of air through the tubes. The inlet should be near the top and the outlet about eighteen inches from the bottom. A convenient place for this tank is in a corner of the boiler-room. From it the air main can be taken underground to the centre of the main shop, and from thence by three vertical branches to the roof trusses, one branch each for the air hoists in the girder shop and structural aisles and one branch with drop pipes down every other column of the centre row, having outlets for the riveting machines, reamers, etc.

All horizontal pipes should be given a slight slope downward in the direction of the flow of air so that any moisture that is carried past the storage tank will not obstruct the flow. At the tank and at all low points in the system blow-off valves must be provided to the drains, and these should be opened at regular intervals. Care in this particular and abundantly large pipes will do away with all trouble from frost in winter. It will not pay to provide special means to re-heat the air before using, and it is not convenient to arrange a satisfactory indirect method.

A low pressure system—about twenty pounds per square inch—will be required for the oil forges. The blower, which will be driven by a small motor, can be supported between the trusses. The distribution system, which will be made of galvanized iron pipes, will be carried over head and down columns near the rivet forges. Ultimately a separate blower will be required for the rivet-making plant and the blacksmith shop, but for the present the one machine will do.

Water Supply System.—Apart from the amount of water required for drinking, sanitary purposes and fire protection, it will only be used for the water-cooler of the compressor, and in the boiler of the heating plant. A 6-inch pipe will supply enough for several fire streams if the pressure is good. The source of supply will probably be a public main on the street to the north of the property. The best place to bring in the private main is along the west boundary. Here it will be always accessible and not likely to be covered up with materials, etc., and furthermore, in case of a break it cannot do much damage to tracks or foundations. Where the first branch in the main occurs a manhole should be

built and a valve placed on both lines leading away from it. In fact it will be found of great convenience to have plenty of valves in the system so that any one section may be cut out with the least possible interference with the rest of the system. It is most important that the supply for the water-cooler on the air compressor be as independent as possible, for the lack of a little water here will practically stop the operation of the plant.

Hydrants should be placed at convenient points, but not too near the buildings. By having them near the tracks they may be used for supplying the locomotive crane. An automatic sprinkler system should be installed in the template shop.

The ends of all branches should be arranged with plugs or caps so as to permit of being extended as the plant grows, and tees should be put in at points wherever there is the slightest possibility that a branch might be needed in the future.

Sewers and Drains.—The drainage system and its arrangement will depend entirely upon local conditions and the amount of fall obtainable. With a minimum grade of ⅛ inch in one foot for a twelve-inch glazed tile sewer it will require three such to properly drain the plant as first constructed. Assuming that they empty into a trunk sewer on the street and that they are to be four feet deep at the manhole in the stock yard, the trunk sewer will have to be at least thirteen feet deep where the drains enter into it. If the depth be a little more than this, something might be saved in cost by running one twenty-four-inch sewer about three hundred feet into the property and connecting the twelve-inch sewers to it. The question of sewers, however, depends so entirely on local conditions that nothing in the way of a definite design can be worked out at this stage. In general, however, it may be said that in addition to providing for carrying off the rain water from the buildings and the sewage, the surface water that may collect on the site must be taken care of. Special care should be taken to keep the sub-grade of the tracks well drained. All pits for machinery and other low spots should be connected with the sewers as well as all drain-offs and drips from water tops, steam pipes, etc. Sewers other than tile drains should not run near foundations if it can be avoided. In case such arrangement is found necessary, then the foundations must be carried down below the level of the sewer. Manholes with catch basins should be built at all junctions of the large sewers.

Fuel Oil System.—Where light fuel oil of a uniform grade and at reasonable price is readily obtainable, its use in riveting heating forges and other furnaces is well worth considering. The rapidity with which a furnace can be heated, the ease in obtaining a uniform temperature, and the absence of the dirt incidental to the use of coal and coke, are all points in its favor. Only satisfactory results can be obtained, however, from a correctly designed system, and while for a small plant the first installation will be expensive, it may be easily extended in the future at very little cost.

The great secret of success with fuel oil is clean oil of a uniform grade, and large distribution pipes. For storage purposes two 12,000-gallon iron tanks will be required. These are to be buried in blue clay near the tracks at least thirty feet from other buildings, so that a tank car may be unloaded into them by gravity. The tanks should have one end exposed in a pit or concrete cellar roofed in to protect it from the weather. This pit should be large enough to contain a small electric pump which will be required to maintain a sufficient pressure in the distribution system. The first tank serves as a receiving and settling tank. The second tank is connected with the first by a pipe so as to draw off the oil a foot or two from the bottom of the first. It will be necessary to drain the sediment out of the settling tank at regular intervals.

The distribution system should not be made of less than 1¼-inch pipe and should form a closed circuit or duplicate system, having a return pipe or overflow back to the second tank. By this means the oil is kept circulating at all times, and congestion from any cause is prevented. If trouble should occur at any point, that section may be cut out by means of valves and the rest of the system need not be interrupted.

For keeping the oil from congealing in winter, steam coils should be put in the storage tanks and the distribution pipes should be laid in iron casing through which steam may be blown.

Heating System.—The question of heating structural steel plants deserves special consideration in each particular case. It is a question that is involved in the choice of a location. To heat brick buildings of ordinary type is not necessarily a very difficult problem. The office can be heated by means of steam coils in the usual way. For the template shop, compressor room and machine shop a hot air system with fan will give satisfactory results if properly designed. This system is cheaper to install than steam coils and interferes less with the arrangement of the benches, machines, etc.

The heating of the main building is a more difficult problem. The volume of air to be heated is so great, uncontrolled by partitions, the conductivity of the corrugated iron and glass which forms the walls is so high, and the large doors have to be opened so frequently, that the cost of a plant that will give satisfactory results is almost prohibitory, to say nothing of the cost of operating it. Then, again, the capital invested in a heating plant lies idle a large part of the year. In fact, in Southern Ontario severe weather seldom lasts more than a few days at a time at intervals during the winter months. Under such conditions a heating plant is not necessary as "salamanders" or open fires burning coke or charcoal can be placed around at convenient points. The cost of such fires, even with the time lost by the workmen in keeping warm added to it, will not equal the interest on a heating plant and the cost of operation.

If care is taken to make a corrugated iron building air-tight, it will be found to be much warmer than such a building is usually expected to be. Large glass areas, such as are becoming so common in manufacturing buildings, if in a south wall, will produce the same warming effect which takes place in a greenhouse. This will add very materially to the warmth of a building on bright days, but it must be counteracted in summer time by good ventilation and circulation of air. Ribbed glass must also be used to diffuse the light.

Erection Equipment.—The equipment required for erecting steel work is merely to be mentioned here to call attention to it as being an item not to be overlooked. Such equipment depreciates so rapidly and the requirements vary so much with every contract, that a large part of the cost of it should be charged up to the work on which it is first used. This should be taken into consideration in making up the estimate for a piece of work. Special equipment, such as travellers, derrick cars, etc., can safely be left for consideration when the time comes to take contracts that require their use.

Order of Procedure in Construction.—When sufficient capital is immediately available the owners will very probably want the plant ready for full operation just as soon as possible, even if it costs more to rush the work. If, on the other

hand, only a portion of the necessary money is to be had at once and it is desired to start manufacturing in a small way at first, then the procedure will be somewhat different.

If at all practicable, it will be best to arrange so that the actual work of manufacturing will begin in the spring or early summer. It will be easier to hold a new organization together during the summer and get them in working order than it will be in the winter. Construction should be started in the early fall so that the water service sewers, tracks and all foundations for buildings may be finished, and the power house and template shop closed in, before cold weather stops the outside work. During the winter the electrical equipment and the compressed air plant can be installed and the template shop fitted up for work. The structural steel for the main building can be erected and the orders placed for the rest of the machinery for delivery in early spring. Orders for raw material should also be put in so that it may be on hand when the time comes to start work.

As soon as the weather permits, the foundations for the machinery may be built and the main building completed. Then, as fast as the machines arrive they may be set up and made ready for operation. In the meantime the template shop has prepared templates and the raw material has been marked for punching; thus gradually the different departments are organized. By the end of May or even earlier, shipments of finished material are being made.

If the above plan of construction is followed, it will be necessary to have another company fabricate the steelwork for the power house and the main building. Or, if desired, only one aisle of the main building may be thus arranged for and the rest of the steel work, including crane, runways and bridges, can be manufactured at a reasonable cost on the spot. This, however, would mean some delay in the completion of the buildings.

THE INFLUENCE OF SILICON ON THE CORROSION OF CAST IRON.*

*By J. Newton Friend and C. W. Marshall (Worcester).

Owing to its relatively low melting point, the ease with which objects may be cast from it, and their extreme hardness when completed, cast iron is now being used for commercial purposes in ever-increasing quantities. It is eminently desirable, therefore, in view of the serious nature of the corroding influences to which articles are exposed, to determine what the influence of varying constituents may be on the corrodibility of cast iron, and to learn what particular compositions offer the maximum resistance to corrosion.

Hitherto but little work has been done in this connection, which affords a wide field for research, inasmuch as the chemical composition of cast iron and the physical conditions at the time of experiment, admit of enormous variation. The problems are in consequence proportionately complicated, and a vast amount of work remains to be done before generalizations of any real value can be made. In the present paper the authors give the results of a study of the influence of silicon upon the corrodibility of cast iron.

For many years chemists have recognized that the presence of alloyed silicon tends to retard the corrosion of iron. Thus Mallett† more than seventy years ago was aware that cast iron rich in silicon is less readily attacked by acids, and Jouve‡ has recently proved that alloys of silicon and iron containing 20 per cent. of the former element are remarkably resistant to acid attack. But alloys such as these are not cast iron, and their utility is greatly restricted by the difficulty of working them on account of the peculiar properties imparted to them by the silicon.

The authors have therefore confined their attention to the influence of corrodibility exerted by a silicon content varying from 1.24 to 2.28 per cent. They would gladly have extended this series had it been possible, but the advantage of studying this particular range is twofold:—(1) It covers many of the various silicon contents usually met with in commercial cast irons and the results are not therefore of purely scientific interest. (2) The silicon is never so great as to interfere with the nature of the carbon content.

The latter is a most important point, and one to which we hope it may be possible to give further attention at a later date. As is well known, the presence of silicon tends to throw out the carbon as graphite, thereby rendering the metal porous and more liable to corrosion. Consequently, unless particular care be taken to keep the carbon in the same condition, both physically and chemically, the influence of the silicon per se upon the corrodibility of the metal must be affected by the proportion of graphitic carbon, and the results rendered misleading. The various cast irons used in this research were especially prepared for the authors by Messrs. Green and Company, of Wakefield, and they have pleasure in acknowledging their indebtedness to the manager, Mr. W. B. Greener, for his kindness. The irons were cut into blocks measuring 4.8 x 1.1 x 1.5 cubic centimetres, and, after rubbing with emery paper, were tested in this form. The authors wish also to thank Mr. A. E. Page, chemist to Messrs. Green and Company, for kindly analysing the metals for them. The results of these analyses were as in Table I.:—

TABLE I.

Cast iron No.	Percentage of Composition. Silicon.	Graphite.	Combined carbon.	Manganese.	Sulphur.	Phosphorus.
1	1.24	2.70	0.65	0.63	0.096	0.99
2	1.20	2.65	0.68	0.75	0.093	1.05
3	1.45	2.55	0.65	0.89	0.082	1.04
4	1.55	2.70	0.67	0.86	0.079	1.02
5	1.72	2.75	0.61	0.75	0.085	1.06
6	2.04	2.60	0.51	0.86	0.115	1.09
7	2.28	2.75	0.55	0.69	0.076	1.04

It will be observed that, with the exception of the silicon, the other elements are present in the cast iron in remarkably uniform proportions. The corrosion of the samples containing the lowest quantity of silicon (No. 1) is in all the accompanying series taken as 100, the corrodibilities of the other samples being expressed accordingly.

I.—Tap Water Tests.—The samples of iron were laid on sheets of paraffin wax in glass beakers containing 500 cubic centimetres of tap water. After seventeen weeks the irons were removed, carefully scraped free from rust, rinsed in alcohol, and dried in a steam oven. They were then weighed, the loss in weight being taken as a measure of the corrosion (see Table II.).

7	2.28	57.6414	5.7614	106

Discussion of the Results.—For the sake of facilitating the discussion of these results, Table VII. has been drawn up, in which the corrosion factors of the cast irons as obtained in the present research are grouped together.

TABLE VII.

Cast iron No.	Silicon. Per cent.	Corrosion factor in Tap water.	Wet and dry.	Salt water.	0.05 per cent. acid.	Mean factor.	Corrosion factor in 0.5 per cent. acid.
1	1.24	100	100	100	100	100	100
2	1.29	81	116	92	105	98	100
3	1.45	101	103	95	100	100	99
4	1.55	100	100	99	98	100	99
5	1.72	99	99	101	104	101	102
6	2.04	95	103	101	104	101	106
7	2.28	88	105	88	101	96	106

A study of Table VII. reveals the following interesting facts:—(1) The corrosion factors for the irons in acids and neutral media are almost identical. This is very remarkable in view of the divergence usually observed between the two in the case of steels. (2) All the irons corrode at a uniform rate, although No. 7 shows a slight tendency to corrode less rapidly in neutral solution. Possibly this indicates that if the percentage of silicon were raised still higher, without affecting the proportions of graphitic and combined carbon, a gradual increase in resistance to corrosion would be observed. We may safely conclude, however, that a variation in the percentage of silicon between the limits of 1.2 and 2.3 per cent. has no appreciable influence per se upon the corrodibility of the cast iron. If the relative proportions of graphitic and combined carbon are simultaneously varied with the silicon, a considerable difference in the corrodibility may be expected, and this is a point upon which the authors hope to throw further light at a future date.

PROSPERITY OF THE BRITISH SHIPBUILDING TRADE.

During the early part of this year British shipbuilding firms had in hand the construction of 563 vessels with an aggregate of 2,063,694 tons. This exceeded by 377,000 tons the vessels on hand last year, and makes the highest record in the history of the British shipbuilding trade.

The tonnage of vessels at present under construction in British shipbuilding yards is equal to two-thirds the entire mercantile marine of Germany, and is about double the entire mercantile marine of France.

WELDING BY THE ELECTRIC ARC.

By J. F. Lincoln.

An arc welder is essentially an apparatus for transforming electric current at high voltage to a low voltage work current with heavy amperage. In a paper read before the American Foundrymen's Association recently, Mr. J. F. Lincoln described briefly a number of types of welder that have more or less satisfactorily established a place for themselves in commercial use.

The changing of the current which is necessary for the best application of the arc is first the reduction of the voltage to a value somewhere between 30 and 60 and then some kind of arrangement so that this voltage will be reduced as the current increases. In other words, as the resistance of the arc decreases on account of increasing current, the amount of current that flows must not increase to a point which will burn the weld or give varying results. That is, the welder must have a dropping characteristic so that as the current flow increases the voltage will drop, and drop considerably.

The first types of arc welder were of resistance units, either a water rheostat or grid resistance which placed sufficient resistance in the circuit so as to reduce the voltage to the proper point for use in the arc. This is a very satisfactory method for arc welding and the only disadvantage is that about 65 per cent. of a 110-volt current and 85 per cent. of a 220-volt current is wasted in the resistance. Another bad feature is the fact that it is rather difficult to handle large currents through resistance in a satisfactory manner on account of the burning-out of the resistance units.

Another type consisted of a motor-generator set, the only possible advantage of which over the resistance method being some current saving. There are many devices of this kind which give a satisfactory arc and save some of the current which was lost in the resistance type. With the motor-generator set it is necessary to keep a considerable amount of resistance in circuit in order to act as a ballast, or to limit the amount of current when only a small amount is required.

The usual application of the electric arc in welding is made by forming an arc between a carbon electrode and the piece to be welded. Since the piece which is welded is the positive electrode, practically all the heat of the arc is liberated here, very little being released at the negative carbon electrode. Into this arc is passed the filling metal which rapidly melts off and drops on to the positive electrode, kept at a welding temperature by the arc. In this way a weld which is perfect can be made because both the filler and the piece to be welded can be kept at a temperature at which the metal is fluid; 95 per cent. of all arc welding is done in this way.

There is another application for the electric arc, however, which is used to some extent in certain classes of work where the weld must be made overhead or on the side of a piece into which the molten metal cannot be dropped. For this application an electrode of metal is used, this electrode itself being the filler. As the arc is established the metal electrode slowly melts off, sticking on to the part already heated by the arc.

This metal electrode work is apt to be unsatisfactory unless carefully done, on account of the fact that the metal welded on must be heated to a welding temperature and the point it touches must also be heated to the same temperature.

In a general way, the statement is true that the weld is equally as strong as the original piece, providing that the original piece is of the same quality and kind of metal as the filler used. This statement, however, does not fully comprehend the difficulties in the way of getting a weld which is as strong as the original piece. A steel casting can be repaired by the use of the arc welder and a weld can be made the strength of which will exceed 60,000 lbs., which is as strong as the average steel casting. The strength of the weld is practically constant when properly made and is approximately 60,000 lbs. per sq, in. Whether it is stronger or weaker than the original piece depends on the strength of the section.

In the cutting of steel, the electric arc has another application. It is used extensively for cutting sheets, boiler-plate, etc. This work can be done cheaply and efficiently when compared with punch press, cold saw, or any other method of cutting.

MODERN METHODS IN THE MANUFACTURE OF PORTLAND CEMENT.

By Mr. H. K. G. Bamber,
Assoc. Inst. C.E., F.C.S., M.C.I., Etc.

The subject matter of this paper has had the close attention of the engineering profession during recent years, in view of the important functions which this material exercises in almost all constructional work. More especially is this the case where the engineer has to combat the mighty forces of nature, which are continually acting on such constructions, more particularly in connection with hydraulic and marine work, such as docks, harbors, breakwaters, water reservoirs, etc., where the combination of forces is such that only the most skilful design, coupled with the use of the highest quality of the most suitable material, can insure success.

To the engineering profession is largely due the credit for the improvement in the quality and adaptability of the material which is the subject of our discussion. By collaboration of their varied experiences in the use of Portland cement, aided by the technical knowledge of the manufacturers, improvements have been introducd into manufacturing processes, which have wholly, or almost entirely, removed the defects which existed in the early days of the manufacture.

Specifications have been drafted as the result of the combined experiences of engineers in all branches of the profession, which have gone far to raise the standard of quality, and to insure uniformity of this most important material of construction.

The general principles governing the manufacture of Portland cement are well known to the profession. It will therefore only be necessary to refer shortly to the usual methods of manufacture, devoting the space at our disposal more particularly to those processes upon the proper conduct of which depends the ultimate quality and reliability of the material produced.

Need of Uniformity in Quality.—Portland cement is now being manufactured in all parts of the world from a variety of raw materials all having as their base some form of calcium carbonate, which, together with suitable argilaceous materials, form the principal ingredients of manufacture. These materials must be perfectly amalgamated and combined chemically in fixed and defiant proportions, the limits of which are not so wide as is generally supposed. Nature

* Notes on a paper delivered to the Canadian Society of Civil Engineers, Vancouver Branch, on May 26th, 1913.

has, in some localities, partially prepared and amalgamated these raw materials, but apparently without any pre-conceived ideas as to the use which such material might ultimately be put, or the stringent requirements of engineers' specifications, with the result that in localities where such partially mixed materials are found, too much reliance is sometimes placed on these ancient natural operations, with the result that cement manufactured therefrom usually has a reputation noted for the variety of its characteristics, and frequently contains one of the principal elements of failure, i.e., want of uniformity. Unless such pseudo-natural raw materials are dealt with on scientific lines, it is preferable that the material operated upon should exist in their elementary condition, having a fixed, definite, and uniform chemical composition, such as pure calcium carbonate, the line in which constitutes the base of the finished material, and clay or shales containing the acid constituents in correct ratio. Given modern machinery for the proper proportioning, amalgamating, and calcining of such materials, and the subsequent reduction, to a fine powder, of the resulting clinkers, a more uniform product can be obtained than by the use of semi-natural materials, where too much reliance is placed upon the reducing and mixing effects of ancient geological operations.

The manufacture of Portland cement has its origin in Great Britain, where suitable materials are found in the greatest abundance. The advancement of chemical science, however, has enabled materials of different characteristics found in various parts of the world to be brought into use. The author has been engaged in British Columbia on the construction of a cement plant at Bamberton on the Saanich Inlet, Vancouver Island, for the Associated Cement Company (Canada) Limited, a company formed by the Associated Portland Cement Manufacturers, (1900) Limited, of England, to operate upon a practically pure limestone, and a clay shale of very uniform composition. With these materials, and with the aid of the modern plant which has been installed, it is confidently expected that cement will be produced of a quality equal, if not superior, to the cement imported from the United Kingdom, the utmost importance being placed on the great desideratum of all engineers, i.e., uniformity of quality.

While describing, with the aid of lantern slides, the general methods of manufacture usually adopted, particular reference was here made by Mr. Bamber to the special additional processes which have been introduced in the new plant at Saanich Inlet, in order to insure the absolute uniformity of quality, the absence of which in the product of many plants has been the cause of much anxiety and trouble to the constructional engineer.

Uniformity in Setting.—There are many factors which help to produce various unsatisfactory results, but perhaps the feature of most importance in the experience of the engineer, and the one in which uniformity is most desirable, is that of setting time. The difficulties of the engineer are great, if during the construction of some important work he is suddenly confronted by a change in the characteristics of the materials he is using, to counteract which might necessitate a reconsideration of his methods of construction, and it should be the aim of all cement manufacturers to supply as uniform a material as possible; so regulating the various properties of their product to suit the climatic and other existing conditions which have a most important bearing on the setting time of all cement which as a chemical product is rapidly affected by changes in atmospheric conditions. The difficulties which confront the cement manufacturer who, having produced an article, the very first quality of which is subject to variation in many of its characteristics due to such atmospheric changes, is not fully realized or understood, and it frequently happens when some difficulty arises in connection with construction, due to such causes, the quality of the cement is unjustly impugned. Long experience has taught the prudent manufacturer how to produce cement which is least affected by such changes, and the methods adopted will be shortly described.

The manufacture of Portland cement necessitates three distinct and separate operations. The first process is mechanical, and includes the assembling, proportioning, amalgamating and grinding the raw materials; the second chemical, during which the material prepared by the first process is calcined at a high temperature, bringing about chemical combination of the various ingredients; the third and final process being partly mechanical and partly chemical, in which the clinker resulting from the calcining operation, together with a small percentage of retarder, is reduced to a fine powder. During the latter operation the cement is submitted to a partial process of hydration by means of steam, at a temperature ranging between 220° and 300° F., and after subsequent cooling the cement is ready for immediate use.

Mechanical Process.—It is essential that the raw materials selected are of such physical character as to be easy of reduction, and such chemical composition that the resulting mixture contains the necessary ingredients in proper ratio, one to the other. If so constituted, and thus available for the purpose, the proportions of the mixture are kept constant by means of continuous chemical supervision, the permissible limits of variation in the composition of the raw mixture being very narrow.

This preliminary part of the manufacture may be conducted by one of three methods, the selection depending upon the physical condition of the raw material to be operated upon.

Where the materials are soft, as in the case of chalk, clay and marls, such as are found in England, the wet process is usually adopted, which consists of reducing the materials together to a pulp, or slurry, containing about 40% water. This is easily accomplished in open wash mills, or pug mills, requiring but small expenditure of power.

When one or both of the materials are of a hard or crystaline character, and in some cases with the soft materials already referred to, the dry process is adopted, which consists of evaporating the water from the raw materials as quarried, and grinding them in a dry state to a fine powder, by means of suitable machinery.

The third process, which is suitable for both soft and refractory materials, has been adopted for the works at Bamberton, Saanich Inlet, and consists of a semi-wet process, in which the drying of the raw materials is avoided—the materials being reduced to a thick slurry in mills suitable also for the dry process, but with a small percentage of water, producing a more uniform and reliable product than is possible with the dry process.

In any of the processes it is essential to reduce the raw material to such fineness that at least 95% will pass through a sieve having 32,400 holes per square inch, more particularly where the materials have not been partially mixed by nature.

A great improvement in the quality of the cement is produced by the introduction at this stage of the manufacture, of such storage capacity and machinery that large quantities of this prepared slurry can be kept in reserve, and continuously mixed, thus correcting any irregularities that may have occurred in the composition of the material during the first mixing and grinding operations. By this means a product

of absolutely correct and uniform composition is presented to the kiln for calcination, and it will be readily understood that, although the cement industry as a whole has not until recently thought it necessary to provide such intermediate storage of prepared raw material, how important it is, before the material is submitted to an expensive chemical process of calculation, in which the desired results are so adversely affected by any irregularity, either in the material or the temperature at which the operation is conducted, that this correcting process should be installed. It is not possible to get perfect chemical combination of the lime with the silicates and aluminates of the clay or shale unless the materials have been reduced to a very fine state of subdivision, and have been thoroughly amalgamated.

Chemical Process.—The calcining or clinkering is carried out in rotary kilns, which with modern practice are increasing in size, now averaging from 150 to 200 feet in length, and from 7 to 10 feet in diameter, being set at an angle to the horizontal of ½ inch to the foot. The raw material is fed into the upper end of the revolving kiln, while the fuel for raising the temperature within the kiln is introduced at the lower end, the raw material passing successively through the three operations of drying, calcining, and clinkering, on its passage down the kiln, the clinker leaving the kiln at red heat. This heat is removed by passing it through rotary coolers, and is used for heating the air for combustion passing into the kiln.

The cool clinker is now ready for the final grinding operation, but before being submitted to this the clinker is stored and mixed under cover in large bulk, so that again any small irregularities of the calcining operations are spread over the product of several days, and thus tend towards uniformity of the finished product.

Final Process.—After cooling and mixing, the clinker, which is material of hard and refractory character, is reduced to a fine powder with the aid of very powerful crushing and grinding machinery, details of which will be explained with the aid of lantern slides. The importance of very fine grinding was not realized until recent years, but its value will be understood when it is known that it is only the impalpable powder of the cement which has any cementituous properties—the coarser particles present being of no more value than their equivalent bulk of sand or crushed rock. It is common practice at the present time to so reduce the clinker that 85% will pass through a sieve having 32,400 holes per square inch, but at the new works at Bamberton, machinery has been installed to enable the cement to be so ground that 95% will pass through this sieve if required. This extra fineness materially increases the cost of production, but adds considerably to the cementituous value of the material. Using this fine ground cement a much richer and stronger concrete is obtained, by reason of the larger quantity of cementituous material present in the very finely ground cement, or on the other hand economies in cost of construction can be obtained by reason of the larger amount of aggregate which such fine ground cement will carry, to produce equal results.

During the process of grinding provision is made for the regulation of the setting time of the cement. Cement clinker ground without any such provision is always very quick setting. The method adopted at the Bamberton works is similar to that now almost universally employed in England, and consists of injecting steam into the tube mills during the final process of grinding together with the addition of a much reduced proportion of gypsum, which is used as a retarder. The effect of this process is to hydrate and thus remove the expansive properties of any loosely combined lime compounds which have resulted from any slight defects which have passed the earlier processes uncorrected, and thus produce a cement which is safe to use immediately after manufacture, even if taken hot from the mill, and by means of this process the setting time of cement can be regulated to suit all requirements.

Extraction of Heat.—The difficulty often experienced by engineers, however, in using hot cement is being provided against by the introduction, at the Bamberton works, of a separate cooling plant, through which all cement as it leaves the grinding mill is passed. This special plant extracts the heat from the cement, reducing it to atmospheric temperature before storage. This is a very important addition to the methods of modern manufacture and, although used largely in Euglish plants, is being introduced for the first time into Canada, or indeed on the American continent, at the plant now being installed. After the cement has been submitted to the process described, it is stored, and mixed in large bulk at atmospheric temperature, before being placed on the market, and it is hoped that the provision which has been made at the new works to produce cement of absolutely uniform quality, will be appreciated by engineers and contractors throughout the western provinces of Canada.

The works at Bamberton are now just commencing manufacturing operations, and will be producing full output of 2,000 barrels per day before the end of June. The works were designed by the Associated Cement Company's own staff, and practically the whole of the machinery was manufactured in England. The work of construction was entrusted to Messrs. McAlpine, Robertson & Company, of Vancouver, under the supervision of the Associated Company's resident engineer's staff; the power for the plant being supplied by the British Columbia Electric Railway Company.

The lecture was illustrated by many interesting pictures of the machinery and plant used in the process of manufacture, all of which were most successfully explained by the lecturer.

PROPOSED FLOATING DOCK FOR VALENCIA, SPAIN.

The contract having been awarded for completing the harbor works of the port of Valencia, the Board of Harbor Works is now giving attention to the matter of docking facilities for the cleaning and repair of vessels, says the United States Consul at Valencia. About three months ago the board proposed to the Government the erection of a small shipyard to accommodate vessels of less than 300 tons. The latest project is a floating dock for handling sea-going ships up to 3,500 tons displacment. Harbor space is too limited to permit of a large dock at this time, according to the system employed at Kiel, Hamburg, Cardiff, Genoa, Barcelona, etc. The tentative plans, therefore, propose the construction on a smaller scale according to the most approved system, but in such a manner as to later permit it to be dismounted and used as a constituent part of the proposed floating dock of 8,000 tons capacity provided for in the approved scheme of port facilities. The details and specifications of the work have not been published, but the preliminary project as submitted to the Ministry of Fomento calls for an expenditure of about £55,000, the dock to be completed in two years. It is hoped that the plans will be speedily approved by the Government, in order to call for bids and award the contract. Engineers and others desiring to learn more about this project can address the Director de la Junta de Obras del Puerto, Sr. Don José Marie Fuster, Valencia.

THE FLAT SLAB SYSTEM IN FLOOR CONSTRUCTION

NOTES DESCRIPTIVE OF ADVANCES IN REINFORCED CONCRETE FLOORS IN PAST DECADE—COMPARISON WITH BEAM AND GIRDER SYSTEM — BEHAVIOR UNDER LOAD

By W. G. URE, B.A.Sc.

THE flat slab system of reinforced concrete floor construction may be defined as that system in which the load is carried from the slab directly into the columns without the use of floor girders or beams, the columns usually being built with a wide flaring top. One of the earliest engineers to make use of this system was Mr. C. A. P. Turner, of Minneapolis, Minn., who first described it in "The Engineering News" October 12th, 1905. In the course of his practice Mr. Turner had found that long span slabs were much more economical in general than those of shorter span and, after building panels up to 24 feet in span, he began to wonder if it were necessary to put in any ribs at all. He investigated the question thoroughly and developed a system of flat slab construction which he called the "mushroom" system. The word "mushroom" is his patented trade-mark, and in using this word to designate flat slabs other than those designed by him, an incorrect use of the term is made. Mr. Turner's patent covers the peculiar arrangement of steel over the column head used in his system, and shown in Fig. 1.

The principle of eliminating all beams and girders was also taken up by other parties, and several other patents taken out regarding it. Probably the first building to be constructed with this type of floor was at the plant of Proctor and Gamble, Armourdale, Kansas, which was built in 1903 from the designs of L. J. Mensch.

The owners and occupants of buildings were quick to appreciate the many advantages which this form of construction possesses, as compared to the beam and girder system. It has come into extensive use, and seems likely to largely supplant the older type, especially in such buildings as warehouses where very heavy floor loads must be provided for.

Since all loads are carried directly to the columns, all reinforcing metal must centre there. The steel is laid in bands about seven-sixteenths of the span in width, a band running along each side of the panel, and one along each of the diagonals. Thus each column has four continuous bands of steel passing over it. Fig. 1 shows the arrangement of the bands. Since the slabs are considered continuous over the supports the metal will lie at the bottom of the slab in the centre of the panel and in the upper part of the slab over the column. The steel passing over the column head is supported on a steel frame which holds the bars in place, takes some direct tension in the top of the slab, and aids in conveying the stresses to the columns. The latter are commonly built with a wide, flaring head in order to keep the shearing stresses down to the permissible values. The structure has been likened to an umbrella at each column, with the rest of the floor suspended from the edges of the umbrellas.

In comparing the flat slab system with the ordinary beam and girder system, the most obvious advantage of the former is the total elimination of projecting ribs below the bottom of the floor slab. Besides being a distinct improvement from the æsthetic point of view this permits a better distribution of light. In any building the light which is reflected from the ceiling is an important consideration. Figs. 2 and 3 show graphically how projecting ribs interfere with this reflection and the even distribution of light obtained with the flat slab system.

It also greatly simplifies the erection of shafting, as there is no interference by beams or girders. In the installation of sprinkler systems great economy results. There is nothing to prevent the water from spreading out evenly in all directions, and whereas it is often necessary to run a line of sprinkler heads down each side of a deep girder, one line would serve the same purpose if the girder be dispensed with.

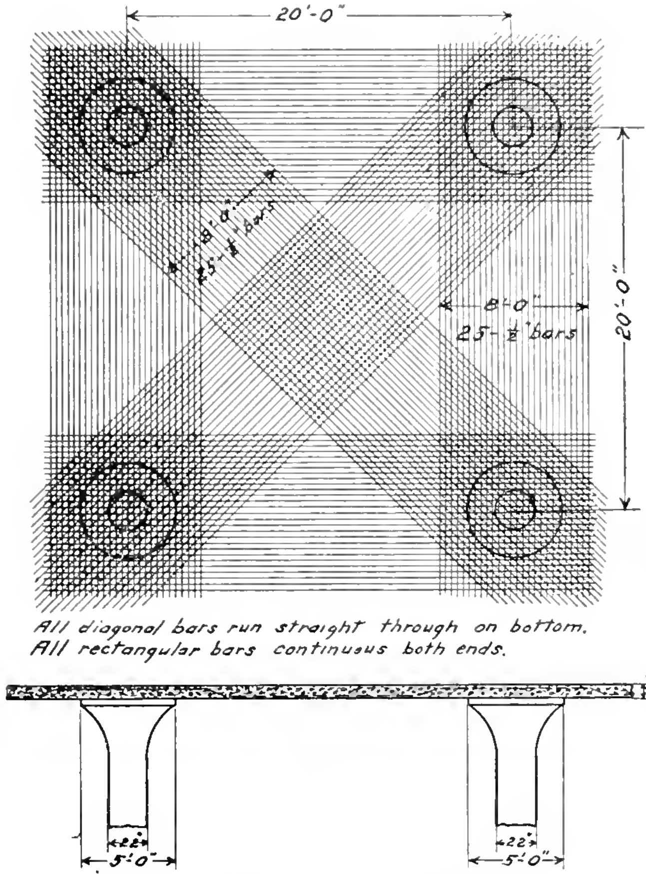

Fig. 1.—Typical Floor Reinforcement.

The height of any building required to obtain a given clear story height is reduced with a corresponding reduction in the cost. For instance, a building for the Toledo Lamp Works was originally designed for a beam and girder system with a 5-inch floor slab, 13-inch x 29-inch longitudinal girders and 10-inch x 23-inch transverse beams at 10-foot centres. The flat slab system finally adopted provided for a floor slab of a uniform thickness of 7 inches. This reduced the story height by 22 inches, which in a four-story building amounted to 88 inches, or more than seven feet. It was estimated that this change in plan meant a saving of from six to seven cents per square foot of floor area. Again, in the Grellet-Collins

building, Philadelphia, the total thickness through the floor was seventeen inches less with the mushroom system than with the beam and girder system. Mr. Turner claims that for a given clear story height it effects an economy of about 10 per cent. of the material in the vertical walls.

In the matter of speed and ease of erection the flat slab is much superior to any other type. The centering is simple and easy, there being no beams to build around. There is no bother with stirrups, and is it claimed that it is easier to make a good bond between old work and new because the concrete is not so deep and the inert material known as laitance does not accumulate to so great an extent.

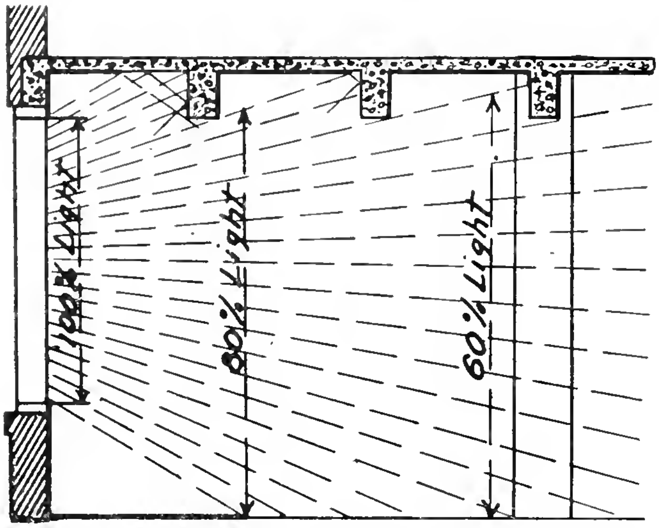

Fig. 2.—Beam and Girder System. Light Rays Reflected by Ceiling are Pocketed by Beams.

Maximum efficiency in reinforcement is attained as the stresses go direct to the columns, not having to be carried round a corner, so to speak. The greatest quantity of metal is over the column head where moment and shear are both a maximum. The concrete is being worked in several directions by the multiple way reinforcement, the distortion in one direction tending to offset and counterbalance that in the other. The metal runs so many ways over the support that the whole structure is tied together, and no failure can occur without adequate warning being first given. The fact that the concrete is concentrated in the slab and that the stresses due to any concentrated load are carried in so many different directions tend to produce rigidity, and to reduce the heavy vibration caused by the working of printing presses and like machinery.

The cost of forms is reduced owing to their simplicity and the fact that they can be so designed that they can be used over and over again without material alteration. In a warehouse built for the Terminal Wharf and Warehouse Company, of Boston, the forms were designed in the draughting room and shipped complete to the site. Since then they have been used in another building. Each panel was erected and removed fifteen times and some twenty, and at the end of that time were still serviceable.

In another instance, assuming the material delivered at the site on cars, and that form lumber could be used twice, the following results were obtained for the cost of forms:—

Floors with beams, girders and slabs..	10 cents per sq. ft.
Slab floor without beams	7 cents per sq. ft.

As to economy, it is claimed that the amount of material required to build a slab or panel that will carry a given test load is less than with any other type. This economy increases rapidly as the load to be carried increases, since the strength of the slab increases approximately with the square of the depth, and hence the relative increase in cost for a given increase in the capacity of the construction is small. In this connection it is well to remember that these floors are considered by many engineers to be lighter, and hence cheaper, than is good practice. However, a reputation has been built for them on their ability to successfully withstand very heavy test loads.

In a paper entitled "The Economical Design of a Reinforced Concrete Floor Panel," Mr. J. Norman Jensen gives cost data for a typical floor panel twenty feet square designed in fourteen different ways. He concludes that of all the designs the flat slab appears to be the most economical. His slab was heavier than Mr. Turner's, being designed by a method requiring considerably more steel. His figures for four of these systems, as illustrated in Fig. 4, accompanying the diagrams, and show a decided economy in the use of the flat slab system, it being 15 per cent. cheaper than its nearest competitor.

In common with everything else, however, the flat slab system has certain disadvantages. The greatest of these is undoubtedly the fact that no adequate theoretical analysis of the stresses in such a floor has ever been put forward, and in consequence there is great uncertainty as to the exact stress distribution within the slab. While this is true it must be admitted that, even at this early stage in its development, it is perfectly feasible to design a flat slab floor and guarantee its safety under the design load, and still maintain a good margin of economy over the earlier types.

Again, the fireproof qualities of the construction have been questioned as the main steel reinforcement in the panel is only protected in most cases by from ¾ inch to 1 inch of concrete on the bottom, a thickness quite inadequate to properly protect the steel in a severe conflagration. Also in a shallow slab of this sort an error in placing the reinforcement is liable to produce more serious results than in a comparatively deep beam or girder. On account of its greater deflection and the flaring column head the flat slab type of

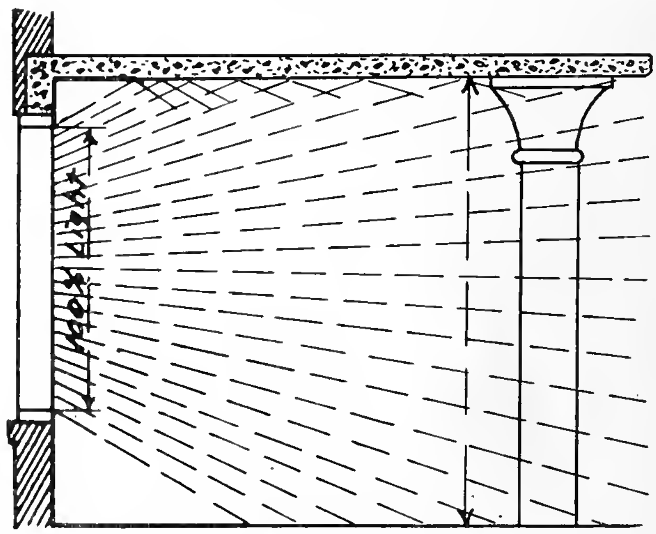

Fig. 3.—Flat Slab System. Light Rays Reflected from Ceiling Give an Even Distribution.

floor is more apt to set up excessive bending stresses in the columns than is the ordinary floor designed in the beam and girder system. Care in the design and in the placing of the steel will minimize these disadvantages.

The Behavior of a Flat Slab Under Load.—It is interesting to consider the manner in which the slab in such a sys-

tem deflects under load, and the nature of the stresses set up by such deflection. Since our knowledge of these stresses is to a large extent based on experimental data, it will be well to describe as briefly as possible a few of the experiments which have been conducted for this purpose.

For a panel square or nearly so it is evident that the face of the slab tends to become a warped surface, assuming continuity over the columns and that the adjacent panels are also loaded. In other words, the slab assumes a dome shape over the column, and a bowl or dish shape in the central portion of the panel. There must then be a line of inflection passing around the column head and dividing off these two regions.

Assuming the slab to be uniformly loaded over its whole area, that part of the slab over the column head may be regarded as an inverted footing supporting a single concentrated load on an area at the centre equal in size and shape to the column capital. The central portion, on the other hand, is like a plate of roughly circular shape supported around the circumference and carrying a uniformly distributed load.

The main stresses would then be in the portion over the column head tension at the upper surface and compression at the lower surface, and in the central portion compression at the upper surface and tension at the lower surface. So, taking a strip of unit width from one column to another, the nature of the stresses would be similar to those in a beam restrained at both ends, and to resist these stresses the steel would be placed as shown in Fig. 1. On account of this restraint it is evident that the columns must be so proportioned that they can resist the bending stresses set up by an eccentric loading such as would occur with one only of several adjacent panels loaded.

Again, a point midway between columns along a line diagonal to the panel will obviously deflect more than a point midway between columns along the side of the panel. This would give rise to tension in the upper part and compression in the lower part of the slab along the side of the panel and in a direction perpendicular to it. These stresses are, of course, of only secondary importance, and the usual method of laying the reinforcement does not make any special provision for them. Cracks along this line, however, formed in numerous multiple panel tests on flat slabs, and even in some cases formed under the dead weight alone, are practical evidence of the existence of this tension.

The Corrugated Bar Company, of Buffalo, have developed a two-way system of reinforcing flat slab floors as distinguished from the usual four-way system, and have adopted the trade-name "Corr-Plate Floors." In this system the diagonal bands of steel are omitted, the entire slab being reinforced by steel placed parallel to the sides of the panel in both directions. One of the advantages claimed for this system is that these tensile stresses can easily be provided for, but as far as the author's knowledge goes it has not come into very extensive use as yet.

It is also probable that in the portion of the slab over the column there are compressive stresses set up along lines roughly parallel to the line of inflection and concentric with the columns due to the doming action; and also similar compressive stresses in the central portion due to the dishing action. These stresses are, of course, taken up by the concrete.

Shear in the flat slab is of two kinds; punching shear, and shear which indicates a tendency towards diagonal tension. The punching shear is a maximum at the outer edge of the column capital, and is due to the capital trying to "punch" a hole through the slab. The diagonal tension has its greatest intensity a short distance out from the column capital.

With regard to moments, the maximum moment occurs over the column, not at the centre of the slab, the critical section being at or near the edge of the capital. The moment coefficient by which to multiply the product of the load and the length, similar to the coefficient "one-eighth" in beams uniformly loaded and freely supported, has not been satisfactorily determined. As a result there are a great variety of moment factors being used. The question of shears and moments will be considered at greater detail elsewhere.

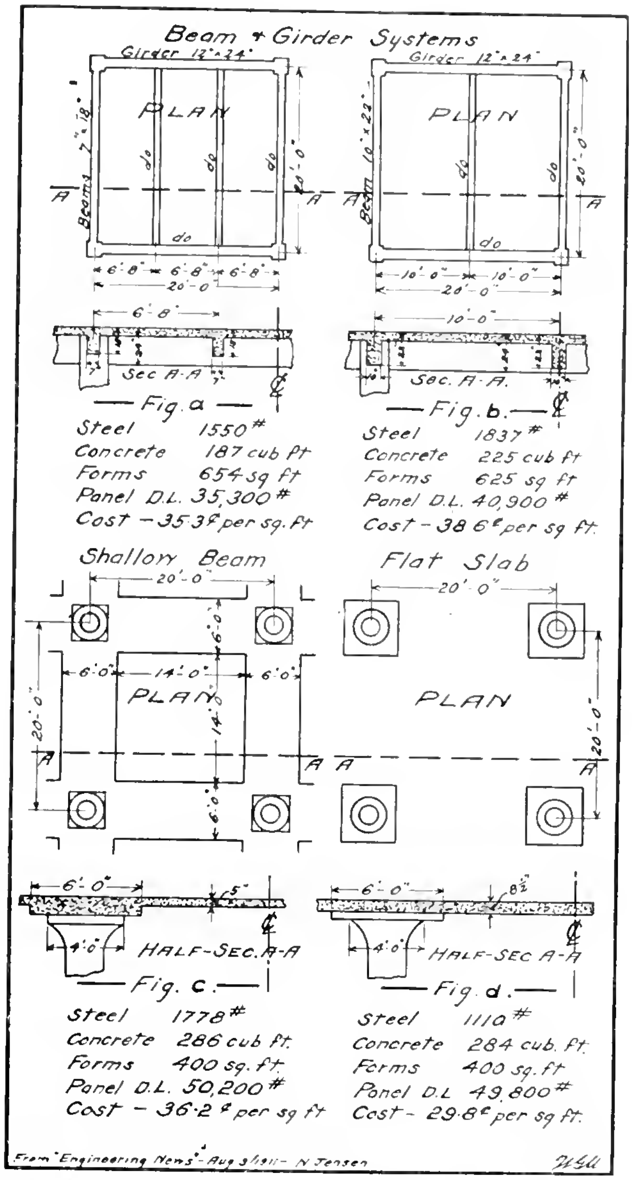

Fig. 4.—Four of Jensen's Fourteen Flat Slab Systems.

Mr. Arthur R. Lord, Research Fellow in the Engineering Experiment Station, University of Illinois, describes in detail a test made by him on a flat slab floor in the proceedings of the National Association of Cement Users, 1911. He describes it as an attempt to carry out a test on a floor in a building constructed under actual working conditions with some of the refinement that can be attained in laboratory testing. The test was made on the fourth floor of an eleven-story warehouse in Minneapolis. The floor was designed for a live load of 225 pounds per square foot, and was of 1:2:4 concrete 9 3/16 inches thick. The panel was 18 feet 8 inches

by 19 feet 1 inch, and was forty days old when tested. Fig. 5 shows the manner of reinforcing.

The deformations in the steel and the concrete at the critical points were obtained by means of extensometers, and from the data thus obtained the various stresses were computed. Mr. Lord claims that the precision attained in his measurements was such that the stresses in the steel were obtained with a maximum error of 1,000 pounds per square inch, and in the concrete with a maximum error of 50 pounds per square inch.

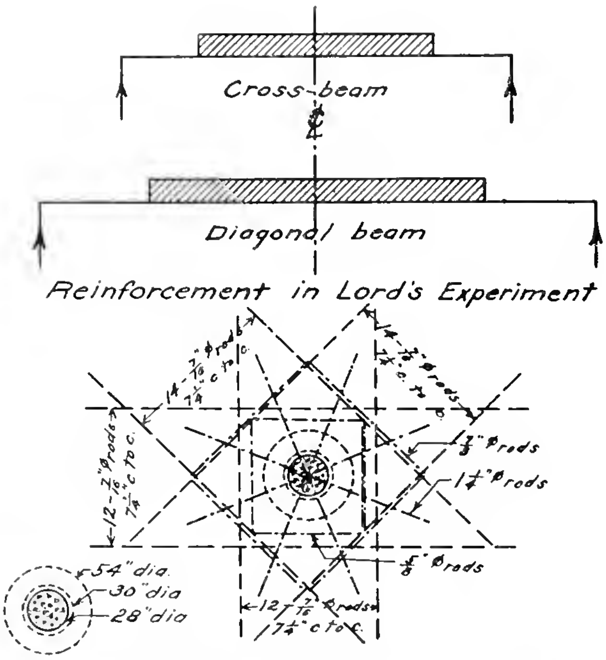

Fig. 5.—Column Used in Lord's Test, Showing Reinforcing.

With regard to deflection it was found that the presence of joints where new concrete is joined to old materially increases the deflection. For eight panels loaded the deflection in the centre panel was 1/1400 of the span, and for one panel only loaded was 1/1200 of the span. Deflections in the central panel were uniformly less than those in the outer panels. The maximum deflection found was at a bulkhead in an outer panel and amounted to 1/1000 of the span.

The stresses in the steel at the centre of the panel were found to be low, running from 2,000 to 4,000 pounds per square inch, and indicating a large amount of arch action reducing the computed stresses. The measurements indicated that the steel in the centre of the panel is most severely stressed for one panel only loaded. The diagonal and cross-band reinforcing were found to be taking practically the same stress, and this stress was approximately equally divided among the individual members of a band. In the steel over the columns the stress reached 16,000 pounds per square inch, so it is clear that this is the critical point in the design of such structures.

For the determination of the stresses in the concrete Young's Modulus was taken as 1,875,000 pounds per square inch. This gave compressive stresses at the edge of the capital of 650 to 675 pounds per square inch. While in this case these values are not excessive, it indicates that care must be taken to provide compressive reinforcement at this point if necessaryy. It is quite common practice to run the diagonal reinforcing straight through on the bottom, thus providing this compressive reinforcement and at the same time avoiding the need of placing four layers of steel in the upper part of the slab near the column which decreases to a considerable extent the effective depth of the slab.

The floor was carefully cleaned and closely examined for indications of cracks. With a load of 265 pounds per square foot faint cracks appeared at a bulkhead. Other such cracks appeared when the maximum load of 350 pounds per square foot was put on. One set ran along the centre of the cross-band, dying out at each end, thus indicating the tension in the upper part of the slab along the side of the panel previously mentioned. Another set appeared around the columns, and 2 inches to 3 inches outside the edge of the capital, furnishing another indication that the maximum moment occurs over the column, the critical section being at or near the edge of the capital.

With regard to the distribution of stress among the several bars of a band of reinforcing, some experiments made on broad, shallow beams by Prof. A. N. Talbot, of the University of Illinois, are of interest. The beams were 36 inches broad, 4 feet 10 inches long, and 3 inches deep, the ratio of depth to width being one-twelfth. They were loaded across their full width and freely supported at the ends for various proportions of their width. The beams were made and tested induplicate at an age of about sixty days.

The following table, from the National Association of Cement Users proceedings, 1911, shows a few of his results:

		Total load carried, in pounds.		
Beam No.	Supported.	Beam No. 1.	Beam No. 2.	Average.
711.1-2	Full width	15,550	15,800	15,675
713.1-2	Half width	15,000	17,000	16,000
715.1-2	Fifth width	14,900	12,250	13,500
717.1-2	Fifth width	14,550	16,000	15,300

All the beams had ten 3/8 inch round rods 3 inches from the face, and beams 717.1-2 had also 1/4 inch round rods on 4-inch centres crosswise of the beam.

From these and similar experiments he concludes that for a beam supported over one-half its width there is no appreciable falling off in the load carried. For a beam supported only one-fifth of the width the decrease in strength is slight. Other tests made by Prof. Talbot on footings, as well as Mr. Lord's extensometer tests, bear out this result.

Prof. Talbot states his conclusion thus: "The width of the resisting section, as governing the stress in the steel, is composed of the width of the pier, plus the depth to the steel on each side of this, plus one-half the remaining width of the footing." In ordinary flat slab designs this would include all the steel in both diagonal and cross-bands, and we may therefore conclude that it is all nearly equally stressed regardless of whether it passes directly over the column head or not. The above discussion refers, of course, to stresses produced by moments only, as the resisting section to shear stresses will obviously only be equal in width to the column.

Mr. C. A. P. Turner's method of design* is based on experimental data obtained from tests made on full-size single panels. Details of particular tests are not to hand, but the general method may be described. Tests were first made on the steel reinforcing and its yield point determined. The slab was then built, using this grade of steel, and after being allowed to season a reasonable time was loaded until the steel reached this yield point, which Mr. Turner claims to be able to recognize from the behavior of the slab. Then, by simple proportion, an exact working load for a given tension in the metal may be determined.

*"Concrete Steel Construction," by C. A. P. Turner, Chap. 3.

In this manner he obtained the formula $\frac{wl^2}{50}$ for bending moment in the mushroom system. His corresponding formula for deflection is $\frac{1}{7000} \cdot \frac{wl^4}{\Sigma Ad^2}$ where

A = the area of one reinforcing rod.
d = the depth of the slab to steel.
l = the span.
w = the total load per square foot of floor area.

This deflection formula is backed up by tests on panels in buildings in which the measured deflections closely approximated those computed from this formula.

Another interesting test was that made on four panels on the tenth floor of the A. J. Franks Building, Chicago, in a manner very similar to that used by Mr. Lord, and hence will only be briefly referred to. A full description of the test, together with tables of measured stresses, are given in the report of W. K. Hatt, consulting engineer, compiled for, and published by the Concrete Steel Products Company, of Chicago. The floor was of the well-known "Cantilever Flat Slab" type, which is the trade-name of this company, analogous to the term "mushroom" used by Mr. Turner.

Under the design load of 256 pounds per square foot the maximum stress in the steel was 4,575 pounds per square inch, occurring in the cross-band over the capital; and the maximum stress in the concrete was 677 pounds per square inch occurring in the drop of a central column. Under a load of 624 pounds per square foot the maximum stress in the steel was 10,095 pounds per square inch in the centre of the span of the cross-band, and the maximum compressive stress in the concrete was 1,685 pounds per square inch in the drop of the central column. The maximum tension in the longitudinal column reinforcing due to eccentric loading occurred at a corner column and amounted to 5,000 pounds per square inch under the design load, and 11,600 pounds per square inch under the maximum load.

The above figures bring out the fact that the design is overbalanced with an excess of steel, that is, the maximum permissible stresses in steel and concrete are not simultaneously realized. This condition probably exists in all present designs for flat slab floors.

BELGIAN COAL PRODUCTION.

The total production of coal in Belgium during 1912 amounted to 22,983,460 tons, against 23,125,140 tons in 1911 and 23,927,230 tons in 1910. This decrease was due to the strike in the Borinage district at the beginning of the year, and also to the limiting of the day's work to 9 hours. Although this fresh decline in production may appear discouraging, it is in reality not unsatisfactory, says the American Consul at Liege, for, in spite of the further reduction of the working day from 9½ hours in 1911 to 9 hours in 1912, there was a decrease of only 141,680 tons, while the production for 1911 was 800,000 tons less than that of 1910; if the strike in the Borinage, which lasted over a month, had not taken place, causing a reduction in the output of 500,000 tons, the total output for 1912 would have been considerably greater than in 1911. The conclusion to be drawn from this is that the limiting of the working day has not had the disastrous results anticipated. The coal mines proceeded to improve their machinery, tools, etc., and the results for 1912 go to show that the increased effective power of the engineers offsets the reduced work of the miners.

GAS AND OIL ENGINES FOR ELECTRIC SUPPLY STATIONS.

By A. N. Rye.

From time to time a number of articles have appeared in the technical press dealing with the generation of electricity by gas and oil engines. Certain of these articles have dealt with private supplies, and have been of considerable interest, but the conditions of public supply are so different from private supply that it is by no means certain that a type of machine which has been satisfactory in one case will be equally satisfactory in the other case; for instance, the question of reliability is of so much more importance to a public supply than to a private plant.

The articles dealing with gas and oil engines for public supplies have, in many cases, been of the nature of estimates, and many engineers are not satisfied that the figures put forward can be obtained in actual practice. Under these circumstances engineers may be interested in the results obtained in a central station depending almost entirely upon gas and Diesel engines, where both classes of engines are run in the same power house by the same staff and under the same conditions.

The public supply of electricity in the Island of Guernsey is undertaken by the Guernsey Electric Light and Power Company, Limited, and was recently described by A. N. Rye in the Electrical Review. The supply was started in 1900 from a small station at Les Amballes, equipped with the plant usually installed about that date, i.e., Belliss engines, Babcock boilers, surface condenser, economizer, battery, etc.

At a later date a demand for power developed in the granite quarries at a distance of about 2½ miles from the generating station; as this load increased it became impossible to deal with it from the Les Amballes station, and a new power station was built at St. Sampson's in the centre of this load, and the Les Amballes station was continued principally to supply the lighting demand in and around the town of St. Peter Port.

TABLE I.—Gas Engines, St. Sampson's, 1912.

Month.	Units generated.	Tons coal.	Lb. per unit gen.	Per ton.	Cost.	Per unit.
January...	51,720	75	3·2	17/10	£66 17 6	·31d.

Total ...	844,876	849·5	2·25		£792 13 11	·225d.

The first plant installed in 1904 at the new station at St. Sampson's consisted of two gas-driven sets nominally of 180 kw. each, together with pressure gas producers and a battery of 1,200 ampere-hours, 420 volts, capacity. Later in 1908 another set of 220 kw. was added. Early in 1911 a Diesel driven set of 165 kw. was installed, and in December, 1912, another similar set was put down. At the old station at Les Amballes, certain steam plant was dismantled in 1911 and two Diesel-driven sets, each of 135 kw., were installed.

Under normal conditions the whole of the load at both stations is carried by the gas and oil-driven plant, the steam plant being used only as a reserve during repairs to the more economical, but less reliable, internal combustion engines.

It will be seen that no engines were installed during 1912, except the last set at St. Sampson's, and this was not running until 1913; consequently in the following figures all the results are from engines which have run at least one year, and the majority for a longer period.

TABLE II.—OIL ENGINE, ST. SAMPSON'S, 1912.

During 1912 the gas and oil engines generated 1,865,236 units, of which rather more than half was generated by the oil engines; consequently both classes of plant had to run for long hours.

Very careful monthly records were kept of the performance of each class of plant, and the accuracy of these figures is proved by the fact that the total of the invoices for coal and oil for the year exceeds the sum of the monthly figures by less than 2½ per cent., and this difference is probably due to small losses in storage, etc.

The figures in Tables I., II. and III., being abstracts from the monthly records, are worked out on the units generated, the units sold not being available each month.

In comparing the performances of the different types of engine, there are certain points to be taken into consideration.

TABLE III.—OIL ENGINES, LES AMBALLES, 1912.

Month.	Units generated.	Weight of oil, lb.	Lb. per unit gen.	Per ton.	Cost.	Per unit.

Total ...	572,675	383,444	·670		£527 5 3	·221d.

In the case of the gas engines, it must be remembered that two of these engines are more than eight years old; in 1911, they had got into a bad state of repair, with worn pistons, worn liners, etc., and it was decided to thoroughly overhaul all the gas engines and gas plant. This work was not completed until July, 1912, and the high fuel consumption of the first three months of 1912 is entirely due to the condition of the plant, and should be neglected when making comparisons. If, then, the months of April, May and June are compared, it will be seen that there was practically no difference in cost per unit for fuel between the gas and oil engines, but later in the year, although the cost of coal increased, the cost of oil increased in much greater ratio, and for the months of October, November and December the gas engines were very decidedly cheaper in fuel cost. This difference in cost is even more marked at the moment of writing, so much so that the Diesel engines are being run as little as possible, and the gas engines as much as possible. This preference for the gas plant is entirely due to the enormous increase in the cost of fuel oil, which has gone up 75 per cent. in price in less than two years.

In Tables II. and III., if the "lb. of oil per unit" column is examined, the wonderfully even running of the Diesel engines will be noticed.

Table III. shows this to most advantage, because the load factor of these engines is more nearly constant from day to day, and also because the engine in Table II. has developed more defects than the engines in Table III., which have run practically without trouble for the whole of the year.

The running of these Diesel engines shows very clearly one remarkable fact—the full load guarantee being .67 lb. of oil per unit, the actual consumption for the year exceeds the guarantee figures by less than 5 per cent.

Everyone who has had to run steam plant under similar conditions knows that the test results will be exceeded by at least 50 per cent., and even with gas plant it is difficult to keep within 20 per cent. of test figures.

It is quite possible to take one or two individual figures in these tables and query their accuracy. For instance, in Table III. the month of July shows an impossibly good figure under "lb. per unit." There are reasons for this, and other small errors, which it would be tedious to explain, and it was thought advisable to give the figures exactly as recorded without any alterations; that any small error in one month corrects itself later is proved by the close agreement with the figures for the complete year.

Table IV. shows the costs per unit sold for 1912 abstracted from the balance-sheet and given in detail, so that the station costs can be seen separated from the distribution costs. It should be mentioned that no part of the cost of the special overhaul to the gas plant is included in these figures.

TABLE IV.—Costs Per Unit Sold for 1912.

Generation—	
Fuel	.33d.
Oil, waste, water, etc.	.08d.
Wages and salaries	.16d.
Repairs—Buildings, plant, tools	.16d.
Accumulators	.05d.
	.78d.
Distribution—	
Wages and salaries, repairs mains, repairs meters, etc.	.08d.
Rent, rates, taxes and insurance	.07d.
Management	.18d.
Total running costs	1.01d.

The above cost is without any interest charges, etc.

$$\text{Efficiency} = \frac{\text{Units sold} \times 100}{\text{Units generated}} = 78 \text{ per cent.}$$

The efficiency figure is given so that direct comparison may be made with the monthly figures which are worked out on units generated; reducing the year's fuel cost to this basis, the result is .257d. per unit generated, the excess over the monthly figures being due to the running of the steam plant under very uneconomical conditions.

The above figures give the facts of the case, but would not be complete without some account of the running of the plant and the opinions formed by the engineers in charge of it.

So far as fuel costs are concerned, there is no doubt that in the special circumstances in Guernsey both gas and Diesel engines are very economical; anthracite peas for gas making can be bought at about the same price as small steam coal, and, in practice, this means that the fuel bill for steam working would be nearly double the cost for generation by gas. The fuel costs of the Diesel engines before the recent heavy rise in the price in oil were practically the same as for gas, but, at present prices, the cost of running the Diesel engines is so heavy, that it is fairly certain that no more engines of this type will be installed until oil prices fall.

Although the internal combustion engines have proved economical in fuel cost, it is certain that part, at least, of this saving must be set aside to pay for the heavier running costs in other directions; for instance, the lubricating oil bill amounts to over 10 per cent. of the fuel bill, and costs probably three times as much as the oil for a steam-driven station using reciprocating engines; while, if turbines are used, this item of expenditure becomes very small. The labor costs are highest for gas engines and lowest for Diesel engines, steam plant taking a position about midway between the two.

As compared with steam, the supervision charges are higher for both gas and oil engines. With internal combustion engines, the repair costs are one of the most serious items, and, in spite of all statements to the contrary, there is no doubt that quite a large amount of the saving in fuel must be spent on repairs.

After two of the gas engines had run for seven years and the third for three years, they had reached such a condition that repairs costing well over £2,000 were necessary to put them in good order, although large sums had been spent on repairs each year. This statement must, however, be qualified by explaining that these particular engines were of an early type, and there is no doubt that more modern engines could be maintained at a lower cost.

The Diesel engines have not been running sufficiently long to require much in the way of ordinary repairs, and for the greater part of the time all breakages have been covered by the makers' guarantees, but from the experience up to date it seems reasonably certain to expect that the repairs will be more costly than for steam plant, though it is hoped that the cost will not be so heavy as for the gas plant.

Reliability is a point of supreme importance for a public supply. Experience with the gas engines showed that internal combustion engines were not suitable for a public supply without the assistance of a large battery, and it is no exaggeration to say that without the battery it would have been quite impossible to maintain the supply with reasonable economy; there are so many things which may suddenly cause a gas engine to give up working, and it is impossible to guard against them. Therefore, either an extra set must always be running in parallel, thus increasing the fuel, oil and attendance charges, or a battery must be installed.

With this experience as a guide, it was decided that when Diesel engines were installed at Les Amballes station, it would be advisable to alter the battery arrangements, so that an output equivalent to the full load of one Diesel set could be available instantly if one of the running sets failed; this precaution has proved most useful; it allows the engines to be run at practically full load with safety, and it has saved a number of failures of supply that otherwise would have taken place.

It must not be assumed from the above remarks that the failures of gas or Diesel engines are always of a serious nature; the great majority of accidents that might cause an interruption to supply are quite trivial, and can be rectified in a few minutes, but they happen so suddenly that there is no time to run up a spare set. With the gas engines it may be a trifling defect in the ignition gear, or something causing pre-ignition or back firing. With the Diesel engine it may be a needle valve stuck open, or a compressor valve hung up; all of these defects may be of no importance, and the engine may be on load again in a few minutes, but unless a spare set is running, or there is a battery, they may cause an interruption to the supply.

Experience has shown that the gas engines are more subject to these little troubles than the Diesel engines, in fact, the Diesel engines have frequently run for several months without an involuntary stop, whereas the same cannot be said of the gas engines. On the other hand, the Diesel engine failures give less warning, and usually take longer to put right.

There is no doubt that, if a supply depends entirely on internal-combustion engines, more spare plant must be installed than in a steam-driven station. In the first place, internal combustion engines cannot be overlooked for emergency purposes, and of even more importance is the fact that a defective steam plant can often be run until the load falls at night, whereas a defect in an internal combustion engine must receive attention without delay. For instance, a leaky valve or a blowing joint on a steam engine can usually wait for attention, but on a gas engine, and more particularly on a Diesel engine, these defects may stop the set at once, and even if they do not do so it is generally advisable to shut down the set without delay to avoid the risk of serious damage, as the high temperature and high pressure of the gases cut the metal surfaces with surprising rapidity and may do much damage in a short time.

Another reason for having plenty of spare plant, particularly with Diesel engines, is the considerable degree of accuracy essential when making adjustments and repairs; this accuracy cannot be obtained on work carried out at night by a tired staff of men racing against time to get the plant on load again.

To sum up briefly, internal combustion engines can give a perfectly satisfactory supply, particularly if batteries are installed; but they are essentially different from steam plant, and must be installed and run with due regard to this fact.

Under favorable circumstances, these machines are economical, but it must not be forgotten that there are other expenses besides the fuel bill, and the fuel bill of the internal-combustion engine must show a handsome saving to justify the use of this class of plant.

Of the two, the Diesel engine appears to have certain advantages for central-station work, but, as long as the market for oil is subject to such severe fluctuations, the use of this engine is likely to be restricted to special cases.

The most useful field for the internal-combustion engine appears to be in small central stations; as the size of the station increases, the advantages of this type of plant decrease, until a point is reached where internal-combustion engines can only pay in exceptional circumstances, and at the present date this point appears to be reached when a

station under average English conditions is of sufficient size to use steam turbines of 1,000 kw. or larger.

The results in Guernsey have fully justified the installation both of gas and Diesel engines, the great saving in the fuel bill being more than sufficient to balance the increased costs in other directions.

BLAST-FURNACE SLAG FOR BRICKS.

Slag bricks are now made by several standard methods, most of them involving hardening either in a steam chamber or an atmosphere of carbon dioxide. During the last few years experiments have been carried out in Germany on the use of slag bricks for engine foundations. The mortar used in these experiments consisted of one part burnt lime and ten parts granulated foundry-iron blast-furnace slag. These materials were thoroughly ground together in a mill, and the brickwork kept carefully moist during building and after being finished. In April, 1912, large cubes were taken from the various foundations and tested under compression. The results varied from 1,166 pounds to 2,688 pounds per square inch, comparing very favorably with best Portland cement concrete. The cost per cubic meter of brick work built of slag bricks with bricks at 17s. per 1,000 was shown to be about 11s 3d. The corresponding cost of concrete foundations varied from about 10s. 6d. per cubic metre for a 1 to 5 mixture to 12s. 1d. for a 1 to 12 mixture. Finally, tests were made on cubes built up of slag bricks hardened by means of carbon dioxide They were built on April 3rd, 1912, using mortar made as before, and were surrounded with moist sand, which was moistened afresh each day for eight days. The results in pounds per square inch were:—

	Test No. 1.	Test No. 2.	Test No. 3.
May 3rd, 1912	2,133	1,835	1,707
June 2nd, 1912	2,290	2,133	1,920

The ratio of lime to granulated slag was 1 to 8 in test No. 1, 1 to 10 in test No. 2, and 1 to 15 in test No. 3.

A GIGANTIC DREDGING CONTRACT.

The contract recently awarded to a Canadian firm for the dredging in connection with the water front development of the city of Toronto under the direction of its Board of Harbor Commissioners is one of the largest ever undertaken in Canada. Some 31,000,000 cubic yards will be removed from the harbor at an estimated expenditure of nearly $6,500,000. Dredging operations will be carried on over the entire water front as far west as the Humber River, and the successful tenderer is getting plant in readiness to undertake the deepening of the harbor immediately. The work of filling the industrial area formerly known as Ashbridge's Bay will be carried on simultaneously. E. L. Cousins, B.A.Sc., is harbor engineer to the Commisssion.

VANCOUVER BRANCH, CANADIAN SOCIETY OF CIVIL ENGINEERS

The accompanying photograph of the Vancouver Branch was taken on the occasion of a visit on May 10th to the Coquitlam Dam which is being constructed by the Vancouver Power Co., Limited. We are indebted to the resident inspecting engineer for taking the photograph, and to Mr. Challies, superintendent, Water Power Branch, Department of the Interior, for copy of it.

REPORT ON INDUSTRIAL EDUCATION.

The report of the Royal Commission on Industrial Training and Technical Education ranks among the most important ever submitted to a Canadian Parliament. If its recommendations are acted upon and properly carried out, Canada's handicap due to lack of technical instruction will in due course assume lesser dimensions. The burden has been long standing. For half a century has been felt the need of a kind of education more closely allied to industry in its many branches. The appointment of the Commission in 1910 was a masterful stroke towards alleviating a growing responsibility.

A section of the report was submitted to the House of Commons last week, and other sections are to follow in the course of a few months. Sufficient has been presented to show that the Commission is of firm conviction in the matter of industrial training. It recommends a number of things, among which is a Federal grant of three millions yearly for the next ten years for foundation purposes, to be apportioned among the provinces on a per capita basis.

Of particular interest to engineers and manufacturers is the recognized need of courses of technical instructions for workmen, foremen, and managers, varying in degree from the general instruction for the increase of skill and ability among laborers, to the improvement of established courses in the existing institutions of highest rank. The decided stand taken on the question of technical schools co-ordinated with the industries, rather than purely trade schools, voices the opinion that practical workshop experience is the better training for thoroughness, speed, discipline and general industrial efficiency among men.

Important among its recommendations is that pertaining to instruction by correspondence from Provincial or inter-Provincial institutions. Canada is woefully behind in this form of dissemination of knowledge. Under the Commission's recommendation a few unfavorable aspects associated with instruction by correspondence would invariably disappear. The frequent visits of qualified travelling instructors to places too small to maintain the services of a permanent supervisor, will likewise tend to remove many of the difficulties and obstacles which arise and for a time hold instruction at a standstill, not infrequently causing a complete cessation of effort.

It is to be hoped that the Dominion Parliament will go a long way towards fulfilling the Commission's recommendations, now that the necessary information is before it. Canada has never had such an exhaustive knowledge of her own peculiar situation in matters pertaining to her capabilities and limitations in industrial training as she now possesses.

THE NEEDS OF THE HIGHER INSTITUTIONS.

The recommendation of the Commission on Industrial Training, which reads: "That existing institutions of college rank should receive whatever additional financial support may be necessary to enable them to adequately fill their place in a national system of industrial training and technical education," will be deeply probed, it is to be hoped. Canadian universities are well known to be struggling through a period of financial embarrassment sufficient to prohibit any development whatsoever towards the increasing demands upon them, and grave fears are expressed here and there of the necessity of an

abridgment in departments already established. If industrial development is the question of the hour, it should be recognized in institutions now sufficiently equipped with qualified instructors and apparatus for the many phases of industrial training harbored within.

The universities and colleges have been making severe raids upon their money-bags to provide technical courses to meet the demands from an increasing number of students and the spread of industry over the Dominion. While these quantities increased, the former became lighter, and the growing inequality has not been adequately recognized by the Government. For instance, the University of Toronto authorities are fully aware of the crying need of a course in Ceramics. Emphasis from the Canadian Clay Products Manufacturers' Association at the time of their recent convention was unnecessary from the viewpoint of apprising the University of conditions in the clay-working industry. Their urgent demands, however, together with others, disclosed the fact that the great institution of learning of the Province of Ontario lacked funds to establish, even on a small scale, a course of instruction to serve their needs, although there was sufficient space available in its laboratories to house such a department.

The rapid growth and development of the country and the further application of science and scientific methods to all forms of production, construction, conservation, and administration, will continue to call for still larger number of graduates. In consequence the universities and colleges are sure to experience further necessity of increased financial support. It is gratifying that the Commission is of the opinion that this should be provided from a source that will not necessitate the fees required from students to be so high as to exclude suitable young persons who may seek the highest grade of technical instruction.

MONTREAL'S TUNNEL PROPOSAL.

A gross revenue of $3,000,000 and a net revenue of $1,500,000 for the first year, with the promise of 12 per cent. profit at the expiration of ten years, all derived from an initial outlay of twenty millions, is the subject of a report received by the Montreal Board of Control from Mr. F. S. Williamson, consulting engineer. The expenditure would provide for an underground tram service, with twelve and one-half miles of two-track lines. He estimates a four-line tube to cost $30,000,000, or $530 a foot, to which must be added the cost of stations.

Mr. Williamson is of the opinion that the trolley car in Montreal is doomed to disappear, and that before many years surface car traffic on business streets will be subjected to prohibitive measures, giving place to motor 'buses and tunnel systems.

The report is interesting in that the congestion of traffic on the central thoroughfares of both Toronto and Montreal are demanding material relief of some kind. The problem of surface transportation is certainly not new in either city, and, although the optimism of Mr. Williamson is to a degree corroborated by the adoption of motor 'buses and tubes in many cities in Europe and the United States, still we are rather inclined to believe that the disappearance from our busy streets of surface cars, with their motive power necessities, is not an affair of the next few decades.

It is stated that the chief engineer has been asked to report to the Montreal controllers on the report.

EDITORIAL COMMENT.

What is claimed to be a record in ground tunnelling is reported in connection with the Canadian Northern Montreal Tunnel and Terminal Company's work in that city. In thirty-one days 810 feet have been completed, the daily progress averaging from 22 to 28 feet per day for the latter part of this period. It will be remembered that the tunnel when finished will exceed three miles in length. Mr. S. P. Brown, managing engineer for Mackenzie, Mann & Co., is chief engineer of the work.

* * * *

The Canadian Northern Railway has been successful in its application to the House of Commons for a further subsidy to aid in the completion of its Transcontinental line. The House recently voted aid to the extent of $15,600,000, all of which, with the exception of $1,000,000, will be devoted to construction work on the line between Edmonton and Yellowhead Pass, B.C. The balance is for the Toronto to Ottawa line. The Temiskaming and Northern Ontario Railway was also subsidized to the extent of $2,000,000, and a bill authorizing the loan of $15,000,000 to the Grand Trunk Pacific Railway was passed.

* * * *

In a recent trade and commerce report the Canadian varieties of graphite were claimed to excel the Ceylon product for a few speciai purposes, and was suitable for many more, providing proper methods were adopted in grading the product. Although no regular trade has been established with the United Kingdom, the statement is encouraging, and if veins of uniform composition can be suitably worked and careful means employed to properly grade the graphite according to quality, Canadian producers will be able to establish a considerable business and satisfactorily compete with the plumbago industry of Ceylon for many purposes. The use of graphite seems to be constantly on the increase, and when the Canadian industry has completely emerged from the many preliminary obstacles which, up to the present, have been a most serious handicap, it is to be anticipated that more definite and systematic efforts will be successful in securing a share of the business open in Great Britain.

* * * *

At the annual Convocation of the University of Toronto on June 6th the honorary degree of Doctor of Science (D.Sc.) was conferred upon Mr. T. Kennard Thomson, who is a graduate of the School of Practical Science, '86, and whose prominence as a consulting engineer is widely known, especially in connection with caisson foundation practice and skeleton steel and reinforced concrete construction in New York City. The honorary degree is a new one in the University of Toronto, and the event is of further interest as it marks the first conference of an honorary degree by this University upon one of its graduates from the Faculty of Applied Science and Engineering or from the old School of Practical Science, and, in fact, upon any follower of the profession of engineering. It will be remembered that the University of Toronto has this year instituted an additional academic degree of Master of Applied Science (M.A.Sc.), open to the holder of the degree of B.A.Sc. who spends an additional year in attendance on a special course of study, upon which work he also compiles a thesis before presenting himself for the examination leading to the degree.

MODERN PIER CONSTRUCTION IN NEW YORK HARBOR

DISPLACEMENT OF WOODEN DECKS OWING TO EXPENSE OF MAINTENANCE — REINFORCED CONCRETE DECK SLABS ON WOODEN SUPERSTRUCTURE—MOISTUREPROOF AND PERMANENT

By CHARLES W. STANIFORD, M. Am. Soc. C.E.

THE present general port activity and agitation for a modernization and expansion of the dock and wharfage system in New York City indicate that at least the community at large seems the realize the necessity of keeping its producing plant, the harbor, up to date and at the top notch of efficiency. There can be no question that New York City's supremacy as a manufacturing and distributing centre is due to wise adaptation of its magnificent harbor. The phenomenal increase in the size of vessels, necessitating longer docks, and the great and constant increase in tonnage entering the harbor, both demand determined action in port development.

New York is approximately equidistant from the ports of Northern Europe and South America. Therefore, it will undoubtedly receive additional impetus in its commerce and shipping on the completion of the Panama Canal. Further, on the completion of the New York State Barge Canal, it will have a direct all-water route to the Great Lakes and the North Middle States and Canada, and the Cape Cod Canal will tap New England commerce.

Harbor Development.—In this period of harbor activity, it will be of interest to both the public and the engineer to describe the gradual development of the harbor, as such development was first systematically undertaken by the city, when, in 1870, the Department of Docks was organized for this purpose, and to show the types of pier construction evolved.

In considering the history of dock development in the city of New York, through the instrumentality of the Department of Docks, it must be borne in mind that, in its early days, the department was greatly handicapped in its progress by the fact that the city actually owned only a very small portion of its great water-front, most of it having passed, by successive water grants, into the control of private interests.

It had been the policy of the New York State Government, prior to the organization of the Department of Docks, to give to corporate interests or private persons grants of land under water in that portion of the present city outside of Manhattan, the object and hope in making such grants being that such cession of land under water would be a sufficient incentive for the investment of private capital in the development of the port.

The hopes of the state and city were fully realized; in fact, they were so generally fulfilled that when the port authority, created by the legislature in establishing the Department of Docks for the purpose of intelligent development under municipal control, began to consider the expansion of wharfage facilities to meet the demands of the growing commerce, it found but little actual water-front in possession or under control of the city.

That the early city authorities used wisdom and foresight in their work of providing for proper expansion of the harbor, is shown by the fact that, through their sagacity and good judgment, the number of piers in the harbor, owned by the municipality of New York, grew from 107 in 1868, valued at $20,000,000, to 232 in 1913, valued at $100,000,000 or more.

There has accrued, therefore, to the city, a return on its investment in this development of the dock system, a large sum of money in increased valuation and annual rent receipts, the latter aggregating in round figures about $4,000,000 per annum, the interest at 4% on a capital of $100,000,000.

It will be seen that, at the outset, the Department of Docks concluded that proper growth and expansion of the harbor under municipal control depended on the acquisition and control of water-front property; and since the organization of the Department of Docks, this has been the policy followed by the city.

When, in 1870, the municipal authorities undertook the burden of increasing the wharfage facilities of the harbor, and of procuring funds for this purpose, it became necessary, as a basis for their work, to determine on some economic form or type of construction, both in regard to the pier structure proper and also the general location with respect to the available shore front, whereby the maximum wharfage accommodation could be developed without excessive or prohibitory cost.

The limited funds available and the small extent of water-front lands under the actual control of the city called for the greatest economy in space, the land requiring intense development in order to obtain the greatest possible extent of wharfage.

Bond issues to be applied to the development of wharfage had to show the same return on the investment, when executed by the city authorities, as if these finances were handled by private parties or corporate interests. Therefore, what might be termed the "principle of economy in expenditure of land and funds" was, of necessity, followed, and this principal was generally adopted by private interests as well, the consequent intensive use of the water front resulting in the adoption of a uniform method of development by a definite system, namely, parallel piers generally at right angles to the general direction of the water-front, with intervening slips wide enough to accommodate vessels of the type intended to berth at the piers.

This parallel system of economically constructed piers, with its resulting economy in space occupied and capital expended, was undoubtedly one of the greatest factors in stimulating the development and expansion of the wharfage facilities in the harbor, and in keeping them abreast of the constant increase in shipping and commerce. It has also created by far the greatest wharfage space of any harbor in the world.

The wooden pier, consisting of a timber deck and floor system supported by timber piles, became the adopted type. It was cheap, durable, and readily adaptable to all classes of shipping. One of the most important characteristics of piers of this type is the ease and economy with which it may be removed entirely, reconstructed wholly or in part, or expand-

* Extracted from Proceedings Am. Soc. C.E., May, 1913; aper to be presented to the society September 3rd.

ed at a low cost, to meet the increasing needs of commerce and shipping. A dock or system of docks sufficient to accommodate the shipping at the time it was built, might be found to be inadequate and obsolete within a comparatively short term of years, a complete re-arrangement being then necessary.

With timber structures, this transformation or reconstruction is a simple, rapid, and economical undertaking; it is difficult and costly with structures of stone, concrete, steel, etc. The use of concrete piles, reinforced concrete substructures or similar forms of construction, therefore, would not only have resulted in high first cost of construction, but the difficulty and expense incidental to the periodical removal, reconstruction, or expansion of dock structures of this type, as necessitated from time to time by the growth of shipping, would have rendered harbor construction work, as a revenue-producing municipal investment, practically impossible, and, consequently, would have greatly retarded the development of the harbor.

Types of Pier Construction.—The United States Government, by virtue of its power to control all navigable waterways in the country, established along the entire water-front or shore line of New York Harbor two lines: one the bulkhead line, which limits the extent outshore of the solid filling or reclaimed land under water; the other, the pierhead line, which determines the limit to which piers may extend beyond the bulkhead line. These piers must be of such construction that the free flow of the tidal water shall remain uninterrupted by the supporting columns. This construction, being a condition wisely insisted on by the Government to preserve tidal conditions and currents, governs, to a great extent, the handling of vessels, particularly of large ones, and affects the sanitation of the city, in that it prevents the accumulation of sewage and refuse which would occur in closed slips. With open slips, such matter is carried away by, and disseminated in, the tidal flow. All pier construction is limited to the area included between the bulkhead and pierhead lines.

The pier which meets these requirements, and was adopted by the city in its early history as the type of structure for berthing vessels (and also adopted by all private and corporate interests), is a wooden structure throughout, consisting of a deck resting on piles driven into the mud or hard bottom. The physical features of the harbor, the geological formation of the bottom, and the condition of the water, fortunately permit the adoption of this type of construction, which, in many other parts of the world, is not adaptable because the life of the timber itself in the water would not be permanent or fairly long-lived. Wood-boring animals, the teredo, limnoria, etc., are very little in evidence, and, therefore, wooden piles are practically permanent below the water-line in almost all parts of New York Harbor.

The prominent objectionable feature to wooden pier construction is the expense necessitated by the constant repairs of the deck sheathing and the continuous wear and tear of the fender system extending along the sides and outer ends of the piers. As to the remainder of the structure, piles, floor system, etc., its maintenance and repair is very economical and consists generally in the replacement, from time to time, here and there, of decayed portions of the timber above mean low water only, at inconsiderable expense.

Until seven or eight years ago, the piers were generally built with decks of yellow pine, 4 in. thick, laid on a system of yellow pine floor structure of ranges and stringers. This deck plank in turn was covered with a second layer of either 3- or 4-in. plank sheathing, laid diagonally or at right angles to the deck proper, to form a wearing surface for the traffic.

Constant repairs and renewal of this deck sheathing, caused by the wear and tear of team traffic, is augmented in great measure by the moisture, horse urine, etc., which saturates the wood and eventually finds its way to the underlying deck and rangers. This forms the greatest item incident to the expense of pier maintenance, the average life of the sheathing for most busy piers being about 6 years, or requiring a 17% renewal annually. As the cost of the deck sheathing is generally about 12% of the total cost of a pier, it will be seen that these sheathing repairs would aggregate 2% per annum of the cost of the entire structure.

New Pier Construction Practice.—Notwithstanding the necessity for constant repairs to the deck sheathing of the wooden pier, the parts of the remainder of the structure—rangers, caps, stringers, piles, and bracing—give excellent service. Maintenance is economical, the average life of the structure above mean low water line being from 20 to 25 years, the repairs aggregating an entire renewal above low water in that period of time. As the life of the piles supporting the structure is practically permanent when submerged below the water, the entire structure can be rebuilt after this period and made practically new by "bench capping" such piles as may be decayed above the water line and renewing the stringers, caps, deck, and sheathing; in other words, the pier structure proper, after a life of 25 years, is readily susceptible of renewal above the water line, the supporting piles below that line being to all intents and purposes permanent.

It will be readily seen that the life of the wooden pier structure would be prolonged still further, and the cost of maintenance and repairs reduced, by the elimination of the objectionable wooden deck sheathing and its replacement by some form of deck impervious to moisture and resisting the wear and tear of traffic.

It was with the object of eliminating this large repair expense incidental to the maintenance of the sheathing, and

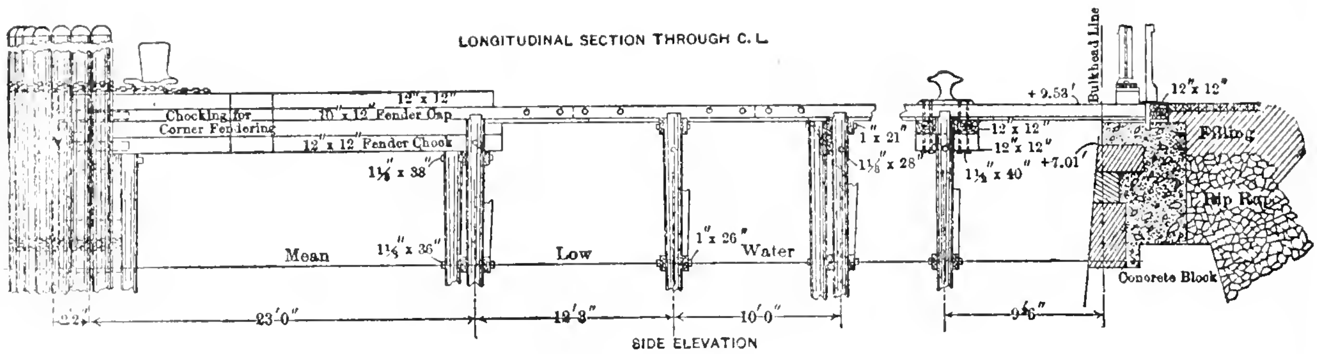

Fig. 1.—Detail of Single Story Reinforced Concrete Deck.

reducing maintenance cost generally, that a serious investigation and study was undertaken of the problem of producing a permanent deck surface supported by timber piles, assumed as permanent below the water line.

This study has resulted in the entire elimination of the old style of wooden deck in new structures, and the production of a new type consisting of reinforced concrete laid directly on the transverse cap system of the wooden pier substructure. This concrete is laid in slabs, spanning the pile bents practically as simple beams.

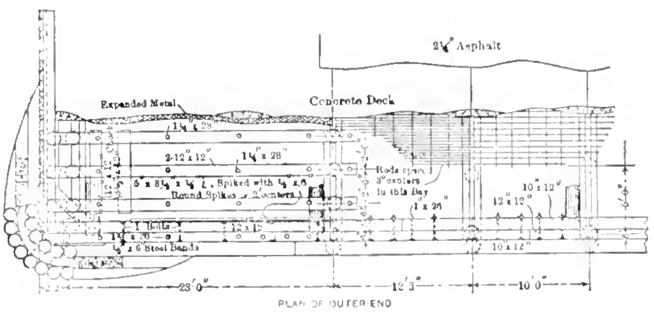

Fig. 2.—Corner Construction Reinforced Concrete Deck.

This new type of deck eliminates not only the 4-in. deck sheathing, but also the 4-in. deck proper and the underlying 12 by 12-in. yellow pine ranger system longitudinally of the pier on top of the transverse cap system, further increasing the life of the substructure.

A structure was thus evolved which had a permanent deck practically impervious to the penetration of moisture to the substructure, readily renewable from low water to the under side of the concrete deck, and permanent below the water line, with a first cost about equal to that of the old wooden deck pier.

The first step in the elimination of the great cost factor, the renewal of the deck sheathing, was the replacing of this sheathing by a concrete wearing surface, from 4 to 6 in. thick, laid directly on the old type of timber decking. This type forms a deck surface which is impervious to moisture, and is, therefore, a protection to the substructure, as well as a saving in maintenance.

The unit of cost of construction of a pier depends in a large measure on the size of the pier. As the outer portions, the sides, and outer end of a large pier are more rigid and heavier than those of a smaller pier, and, therefore, cost more in both labor and material, the relative cost per square foot of a short pier is considerably larger than that of a long one. The average cost of the old wooden deck pier of large dimensions is from $1.00 to $1.15 per sq. ft.

Further investigation and study resulted in the entire elimination of the wooden deck plank, deck sheathing, wooden floor rangers, etc., and the adoption of the present type of pier deck, as before mentioned, consisting of a reinforced concrete slab, 10½ in. thick, extending from centre to centre of the transverse pile rows placed generally 10 ft. apart. This slab is designed to carry a live load of 500 lb. per sq. ft. for the 10-ft. span between pile rows, and is reinforced with ⅝-in. square steel rods. The latter run longitudinally of the pier, are 6 in. apart, and are staggered so that only alternate rods terminate on the same pile row, with ⅜ by ⅜-in. separating rods. The slab is of 1:2:4 Portland cement concrete, with ¾-in. broken stone, the upper ½ in. of the slab being of Portland cement mortar finished smooth. This rod reinforcement is intended to be standard, but the substitution of trade sizes of equal strength and efficiency is permitted, subject to approval.

Definite illustrations of this type of pier construction are found in the two new piers recently completed by the Department of Docks and Ferries at the Gowanus Section, South Brooklyn, one at the foot of 31st Street, 1,475 ft. long, and the second at the foot of 33rd Street, 1,616 ft. long, each pier being 150 ft. wide. These piers are among the finest in the harbor, and are probably the largest of their type in the world. The unit cost is practically the same as that of the old wooden deck type. The decks have a crown of about 8 in., in order to shed the water. The in-shore end of the concrete deck rests on the bulkhead wall, but is not attached thereto, a horizontal plane joint allowing the deck to slide on the wall as it expands or contracts on account of changes of temperature.

Twenty-six piers with concrete decks have been built by the department during the past seven years. The earlier type, as exemplified by the Chelsea Section piers, consists of a 6-in. concrete deck surface reinforced with expanded metal and laid directly on the deck planking. The next type produced omitted the deck plank, and is represented by eight piers with decks consisting of a concrete slab, 6½ in. thick, reinforced with expanded metal, the slab spanning yellow pine rangers running longitudinally of the piers and generally about 6 ft. apart.

The final type evolved, omitting the timber floor system entirely, and placing a concrete slab reinforced with longitudinal steel rods directly on the timber-capped transverse pile rows, is represented by eight piers, the most important examples being those at the foot of 31st and 33rd Streets, South Brooklyn, and the Municipal Pier at Stapleton, Staten Island.

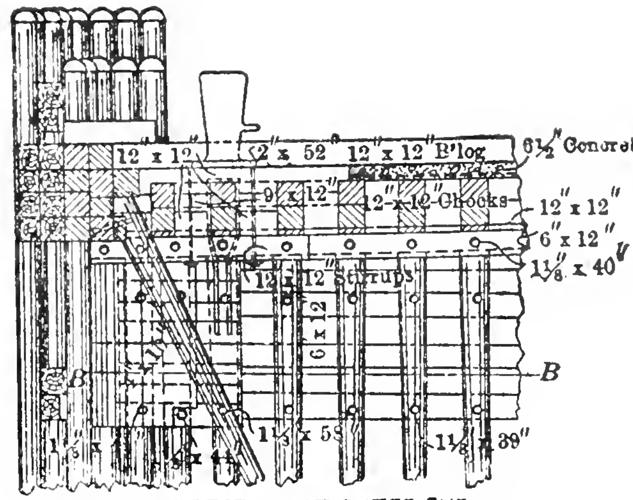

Fig. 3.—Pier Construction With Reinforced Concrete Deck.

All these piers have been built where the condition of the river bottom underlying them was such that no settlement could occur, and they have behaved admirably. No repairs have been necessary, except to the fender system, and none are anticipated for many years to come, excepting the renewal here and there of an imperfect pile, where rot may appear above the water line. Such renewals can be made at a minimum of cost—a few dollars per pile—by bench-capping, without any interference whatever with the integrity of the reinforced deck itself.

Column Foundations.—For single-story sheds, where additional bearing strength is required in the new concrete deck pier for shed column or superstructure support, the question

has been treated in general in the same manner as in the other parts of the structure, that is, by adding the necessary number of piles to carry the load concentrations, assuming the piles to be permanent below low water and easily renewable above that plane.

Concrete Deck Pier.

Cost of construction, 31st Street Pier, South Brooklyn, no asphalt surface	$0.87 per sq. ft.
Cost of construction, 33rd Street Pier, South Brooklyn, with asphalt surface	0.97 per sq. ft.

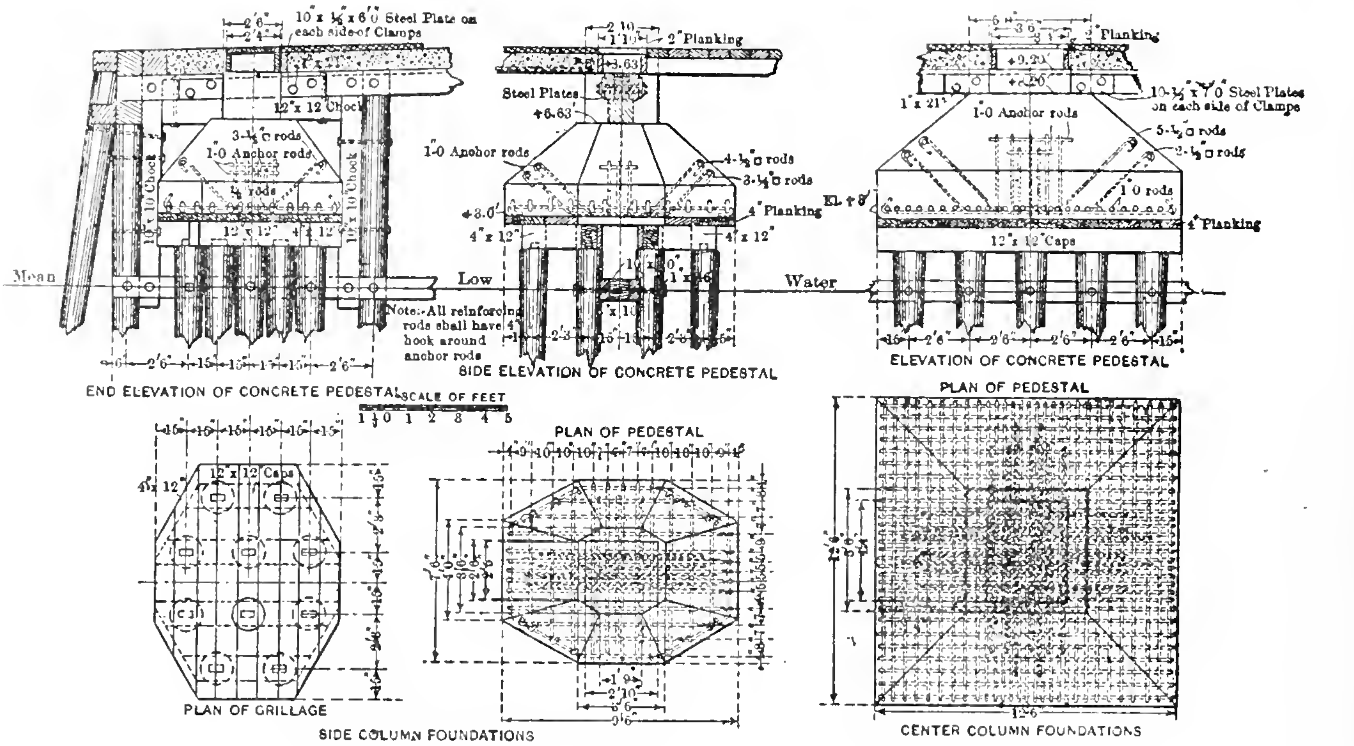

Fig. 4.—Details of Reinforced Concrete Deck and Column Pedestals, Two-Story Shed.

Where heavier concentrations occur, as, for example, in double-deck or two-story sheds, the piles are cut off at or near low water and covered with a timber grillage; built on this grillage are reinforced concrete pedestals, extending to the deck level, to carry the shed columns.

Railroad tracks, being a requirement on the South Brooklyn piers previously described, are carried on four lines of 15-in. steel I-beams, placed on the transverse clamp system of the pile rows and extending from the in-shore end of the pier sheds to within 60 ft. of the out-shore shed wall. The beams rest on steel saddles placed on the clamps, and are entirely encased in concrete.

Cost of Construction, Maintenance and Repairs.

Average Cost of Construction of Wooden Deck Piers, $1.00 to $1.15 per Square Foot.

Repair Costs of Wooden Deck Pier.

Description.	Percentage of total original cost.	Renewal required.
Sheathing	12	Every 6 years.
Backing log	1.8	Every 8 years
Fender chocks, including vertical sheathing	4	Every 10 years.
Fender piles	4.7	Every 12 years.
Decking	11.3	Every 15 years.
Bracing	7.1	50% in every 20 years.
Rangers and caps	24.4	50% in every 20 years.
Piles*	34.7	33⅓% every 20 years.

*Above M.L.W. only.

Economy being a prime factor in its construction, it was decided to try out the concrete deck surface for wear and tear of heavy team traffic, and the earlier decks, therefore, were finished with a smooth mortar surface to receive this traffic. Two years of experimenting on these lines, determined the fact that though the concrete surface was admirably adapted to light traffic, cargo handling by hand or

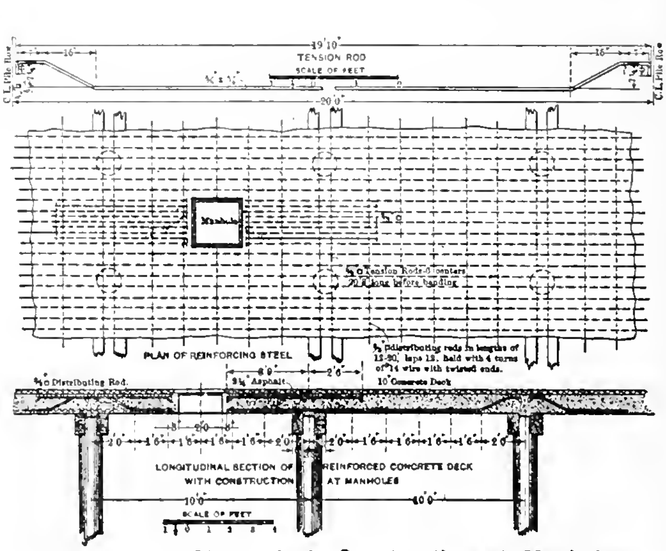

Fig. 5.—Two-Story Shed—Construction at Manholes.

motor trucks, etc., it could not stand the concentration of heavy team traffic confined within narrow lanes located generally in the centre of the pier. The grinding and turning of heavily laden trucks inside these narrow lanes or zones gradually caused surface rupture of the top coat of mortar.

It was decided, therefore, to place an asphalt wearing surface on the deck, and this has proven very effective.

The piers, at the foot of 31st and 33rd Streets, South Brooklyn, have been in service for about three years. No signs of cracking or other imperfections have appeared, and the piers, as a whole, are a complete success.

Repairs.—For the modern type of concrete deck pier, the cost of maintaining the fender system is about the same as that for the wooden pier; deck sheathing repairs are practically eliminated, except such minor asphalt patching as may be required, and can be considered negligible in a good asphalt deck under cover; the deck plank is eliminated; the life of the ranger and cap system is prolonged by the protection from moisture given by the impervious concrete deck, and the cost of maintenance and repairs, therefore, is reduced to a minimum.

(c) The supporting part, below the water line, is permanent; and

(d) The resulting structure is such that it can be readily extended, reconstructed, or, if necessary, entirely removed at a cost not prohibitive, as would be the case, for example, with most types of reinforced concrete deck-supporting structures.

II. That the department has produced permanent parts in the structures where these are essential. No attempt was made to obtain absolute permanency above low water, in the structure supporting the deck, for the reason that.

III. This portion of the structure, the caps, piles, braces, etc., protected as they are from saturation by urine and other objectionable fluids by the concrete and asphalt deck forming a protecting roof, can be maintained in good condition at a very low cost.

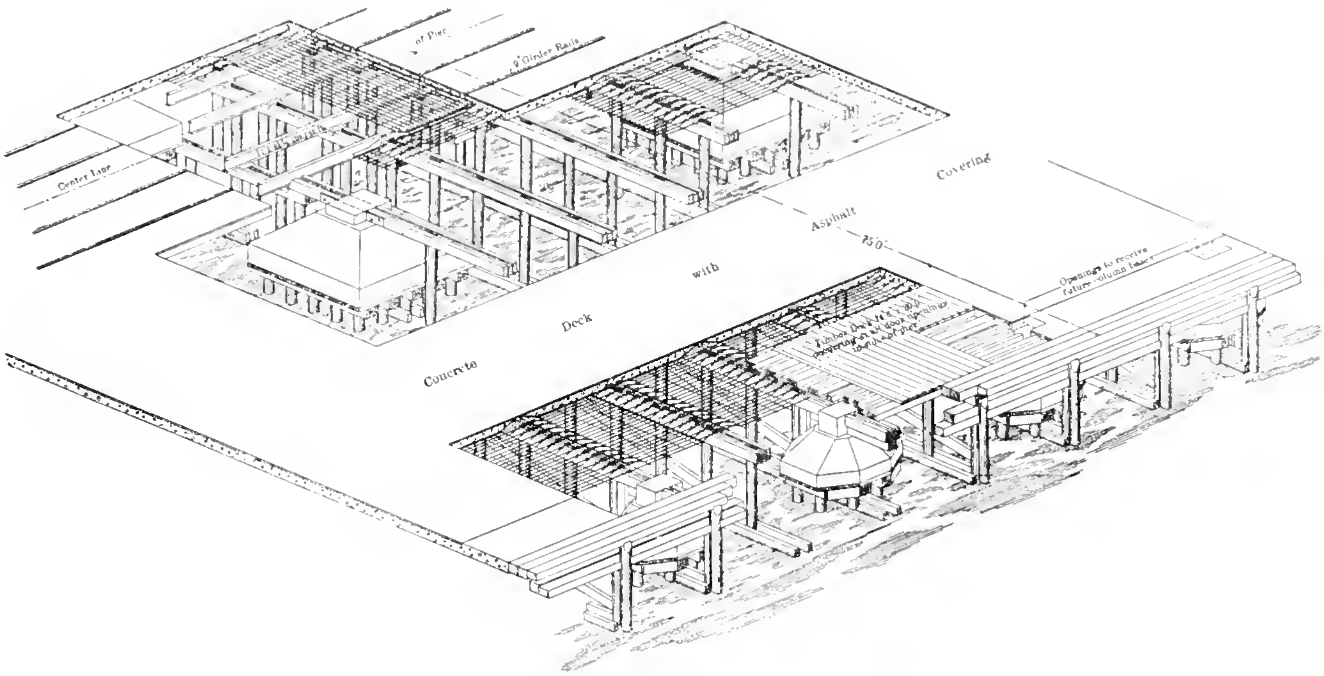

Fig. 6.—Showing Placing of Steel Reinforcement, Pedestals, Track Beams, Etc., New York Pier Construction.

Conclusions.—From the foregoing it will be observed that the problem which confronted the department was the elimination of the timber deck and deck-supporting structure of the wooden pier, by the substitution therefor of some permanent form of construction meeting the following requirements:—

(a) Economy in cost of construction and maintenance, the unit cost to be such as to produce or make possible a remunerative return on the capital invested.

(b) The construction to be of such character as to be readily extended, reconstructed, re-modeled, or, if necessary, entirely removed, as more intensive development of the area occupied by the pier or system of piers might be made necessary by the growth of commerce and shipping.

From what has been stated the following conclusions may be deduced:—

I. Admitting that timber piles and foundation work are generally permanent below the mean low water line in New York Harbor, the Department of Docks and Ferries has met the requirements of the problem by producing piers having the following characteristics:—

(a) The deck is absolutely permanent;

(b The substructure, above mean low water, is easily and cheaply repaired and maintained;

IV. The type of structure produced, approximating permancy, is now being built by the department at a first cost no greater than that of the former type of wooden pier throughout, and the cost of repairs and maintenance of the deck structure is almost entirely eliminated.

SELECTION OF SAND FOR CONCRETE.

The two most essential qualities to consider in sand are cleanness, that is, freedom from impurities, and coarseness of the grains. The sharpness of the grains and the mineralogical composition, according to "Concrete Costs," by Taylor and Thompson, while affecting to a slight extent the strength of the mortar for concrete, are not in themselves sufficient for accepting or rejecting a sand.

Cleanness, meaning by this not so much freedom from fine, clayey material as freedom from vegetable matter, is of prime importance, since such impurities may so affect the strength of the mortar as to make even a well-graded sand absolutely dangerous to use. The fineness of the sand and its percentage of silt passing a sieve having 100 meshes per linear inch, may also be a ground for rejection, since a fine sand always makes a weak mortar or concrete.

DETERMINATION OF WATER IN COAL.

By P. L. Teed.

At first sight the determination of water in quantities of coal would appear to be a simple operation in the hands of the assayer, and because of its simplicity one would expect great accuracy in the operation. In a paper read at a meeting of the Institute of Mining and Metallurgy, Mr. Teed makes clear, however, that the task does not admit of such accuracy as one might suppose. In his paper he endeavors:—(1) To show that in the simple drying method universally employed for determining the percentage of moisture in a fuel, reactions other than the simple volatilization of the water take place, which may materially affect the accuracy of the result, and (2) to describe an accurate and rapid though more complex process for determining the percentage of moisture in fuel. The method universally employed is that of taking a weighed quantity of 80-mesh coal, drying the same in a steam oven, and recording the loss in weight, but sources of inaccuracy exist due to the following reactions:—(a) Oxidation of pyrites making the result too low, (b) volatilization of matter contained in the coal making the result too high; and (c) oxidation of the coal itself making the result too high.

The following method has been evolved:—The apparatus, consists of a 100-cc. pressure flask, a "U" tube, of about ½-in. bore, and a sulphuric-acid drying tube, all of which must be capable of withstanding atmospheric pressure; besides these, sound rubber corks and some form of vacuum pump are necessary. With regard to the latter, the Sprengel water vacuum pump worked off the main supply has been found to give a reduction in pressure equal to about 725 mm., and to be in every way satisfactory.

The employment of the apparatus is as follows:—In the dry weighed flask a quantity of finely divided coal (80-mesh) is placed, and the weight of the same determined by difference; this flask is connected to the weighed "U" tube, whose limb nearest the flask is filled with lump quicklime, while that more remote is filled with finely-ground quicklime; this "U" tube is connected to the sulphuric acid drying tube, which is itself joined up to the Sprengel pump with an intervening tap. The pump is started and a vacuum gradually created (the speed of the outcoming gas being shown by the bubbles in the sulphuric acid drying tube); the flow of water through the pump is gradually increased, until a vacuum of about 700 mm. is created; then boiling water is poured into the beaker in which the flask containing the coal is standing, while to the beaker in which the lime tube is situated, a boiling aqueous solution of either sodium chloride or calcium chloride is added, care being taken that the corks of the tube are not wetted with the solution. The reactions taking place are as follows:—

Under the reduction of pressure and at a temperature of the boiling water surrounding the flask containing the coal, the water in the coal, together with volatile matter varying with the nature of the coal, distils off and passes into the lime tube where, in accordance with the following equation—

$$(CaO + H_2O - Ca.OH)_2,$$

the water originally in the coal is chemically retained, while the other volatile matter from the coal, owing to the absence of any chemical affinity for the lime, and the higher temperature of the lime tube (due to its being surrounded by a boiling aqueous solution of sodium chloride or calcium chloride), passes through to the sulphuric acid drying tube, where some of it is retained, discoloring the sulphuric acid, while other portions pass through to the pump.

At the end of about half an hour, the whole of the water having passed from the coal to the lime tube, the tap adjoining the vacuum pump is turned off, the beaker of boiling water surrounding the coal flask is removed, and the air gradually let back through the sulphuric acid drying tube into the apparatus; then the apparatus is taken to pieces, the lime tube washed, wiped, placed in a desiccator to cool, then weighed, the increase in weight noted (this increase is solely due to water from the coal) and the percentage of water in the coal calculated.

In the new method the two errors due to oxidation no longer exist, because the water is distilled from the coal in the absence of air, and consequently no oxidation can take place; with regard to the error due to volatilization of matter in the coal, something more must be said, for the volatilization still takes place, but since the temperature of the quicklime tube is higher than the coal itself, no condensation can take place in this tube unless chemical action takes place.

When determining the percentage of moisture in an anthracite, it was found that the increase in weight of the drying tube was greater than the loss in weight of the anthracite in the coal flask, by an amount far greater than would be accounted for the fact that the aqueous vapour in the air originally in the apparatus would be absorbed by the drying tube; naturally it was at first supposed that there must be some leak in the apparatus between the coal flask and the drying tube, but this, on performing a blank experiment, was not found to be the case.

The experiment was repeated, using anthracite in the coal flask, and it was found that while the increase in weight of the drying tube was equal to 2.78 per cent. of the anthracite employed, the decrease in the weight of the anthracite in the flask was equal to 2.52 per cent. This curious fact having been undoubtedly established, the author sought for some explanation of it, and could but conclude that when the water left the coal under the influence of the reduced pressure and heat, it left it in the physical condition of charcoal, capable, like charcoal, of absorbing many times its own volume of gas.

PRODUCTION POWER PLANTS.

The United States Bureau of Mines has published a study of the producer-gas plants using anthracite. Such a plant has large conservation and commercial possibilities. Government experiments for eight years have demonstrated not only a very low fuel consumption per horse-power hour, but also the possibility of utilizing commercially low grades of bituminous, lignite and peat.

There are in present use engines with aggregate capacity of 200,000 horse-power deriving this power from producer gas. Engines with power from blast furnace and coke oven gas aggregate 350,000 horse-power. The latter type is largely in steel works, the power being used for mills and furnaces.

There are producer-gas plants in 46 states, the District of Columbia and Alaska. From 1909 to 1912 such plants increased from 474 to 722, or 52 per cent. Horse-power increases from 11,250 to 187,140, or 68 per cent. Plants using anthracite increased from 415 to 610 and their power from 48,100 to 89,470; those using bituminous from 37 to 77 and power from 54,150 to 86,605; those using lignite from 23 to 32 and power from 9,000 to 10,230.

The producer-gas power plant has proved economical in obtaining power and in using fuels such as peat and lignite. Texas in 1912 had 28 producer-gas power plants, of which three used bituminous coal, six used anthracite and 19 used lignite.

CONCRETE CULVERTS.

By F. H. McKechnie, B.A.Sc.

(Continued from last week, p. 827.)

The Old Rail Culverts.—The old rail culvert is not one in very general use, but is used, more or less, as a substitute for the regular reinforced beam or arch culvert. The Oregon Short Line Railroad uses box and arch culverts reinforced with steel rails.

In the box culverts the rails in the cover plate are spaced close together under the tracks and further apart towards the ends. The rails are all set base downward and the side walls are well battered to give wide footings.

In the arch culverts the rails are laid alternatively base and head downwards and are bent as nearly as possible to the shape of the arch. The spacing of the rails is the same as that for the box culverts. Under the centre, where the spacing of the rails is closest, two parallel strips of expanded metal are embedded on the intrados. The side and wing walls are braced together by cross walls of concrete, thus holding the filling of gravel or rocks in the invert.

The concrete used in the culvert is mixed in the usual proportions of one, three, six for such structures, Portland cement and broken stone being used.

I-Beam Culverts.—This is a type of culvert quite extensively used on the Canadian and American railroads, and is particularly used and useful where a wide culvert opening is necessary on account of a low elevation of grade above stream bed and where a large waterway is needed.

The accompanying figure (Fig. 9) shows a construction adapted for culverts, cattle passes, drainage ditches, etc., ranging from ten to fifteen-foot spans. The arches are usually quite flat, the twelve-foot arch having a radius of sixteen feet for a chord of twelve feet and corner curves of two-foot radius to the face of the abutment, which has a batter of one in twenty-four.

Fig. 9.—Typical Railroad Culvert With 10-Foot Opening.

For single track the length of the culvert is nineteen feet, and twenty feet and a half over the parapet walls. The thickness of the concrete at the crown of the arch is eighteen to twenty-three inches and five lines of ten to twelve-inch I-beams, sixteen feet long, spaced two feet apart, are placed under each track, embedded in the arch with about three inches of concrete below and eight inches above at the crown.

The upper surface of the arch is made to form, with the parapet walls, a basin or trough in which the ordinary ballast is laid, thus allowing the roadbed to be continued unbroken over the structure. The wing walls may be built straight or flaring, as desired. The invert is laid with a twenty-six-foot radius and scouring may be prevented by apron walls at the ends.

The culvert shown is one of this type with a ten-foot opening, and contains about one hundred and ninety yards of concrete.

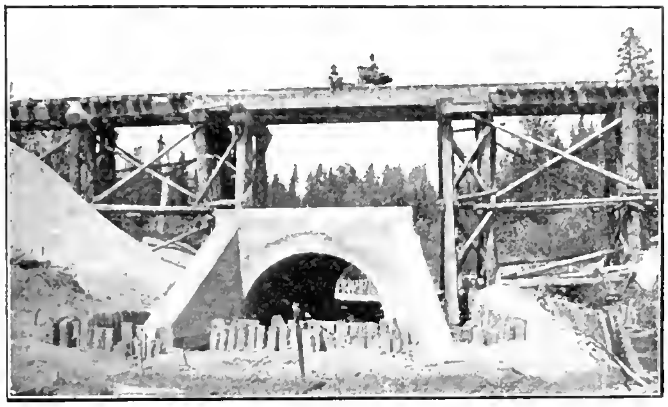

Fig. 10.—Typical Railroad Culvert in Earlier Stage of Construction.

The Box Culvert.—Flat slabs for culverts resting directly on the abutments are used in spans of from four to sixteen feet. Box culverts for railroad work are similar to highway culverts, but must be built to carry the greatly increased loading coming upon them. The side walls are usually reinforced so as to withstand earth pressure due to dead and live loads. When the abutments are sufficiently heavy at the base for this wall, it may be designed as a simple slab supported at top and bottom. Thus the walls may be greatly reduced in thickness over what is required for a wall of plain concrete.

It is frequently, depending on the material on which the culvert is built, necessary to carry an inverted slab continuous between the side walls to provide ample bearing for the heavy loads coming on these foundations. When such a floor slab is used it should be of the same strength as the cover slab, with the bars inverted in the top of the slab. Wing walls, when used, may be designed the same as for an ordinary retaining wall.

In calculating moments in box culverts of this type, a live load is assumed of 50,000 pounds on axles, five-foot centres, and 10,000 pounds per foot of track. This load may be taken as distributed uniformly over ties eight feet long The manner in which the live load will be distributed when it reaches the culvert cover will depend on the character of the embankment.

It may be assumed that the line of zero stress in the embankment, due to live load, follows a slope of one-half to one, which is much more nearly vertical than the ordinary angle of repose. For fill of less than two feet, the impact allowance should be one hundred per cent., between two and four feet, seventy-five per cent.; above four feet an allowance of fifty per cent. may be made.

Let P_L = unit pressure on cover per square foot due to live load.

Let P_D = unit pressure on cover per square foot due to dead load.

Then $P = P_L + P_D$

Total load per linear foot = 10,000 pounds, and adding 50 per cent. for impact = 15,000 pounds.

$$15{,}000 = P_L \left(\frac{8 + h}{2}\right) \text{ or } P_L = \frac{30{,}000}{h + 16}$$

$$P_D = 100h$$

$$P = \frac{30{,}000}{h + 16} + 100h = \text{total superimposed load per}$$

square foot on cover.

The beam culverts similar to those described are often used where the arch culvert might just as well be employed. The argument most often advanced by advocates of the beam culvert, as compared with the arch, is increased waterway. Other possible advantages are a simplicity of arrangement of false work and a greater ease of analysis. Taking up this last argument, while it is admitted that the reinforced beam is a comparatively simple structure and the arch a very complex one, it will be shown, nevertheless, that there is no such advantage, since an arch designed by the very same method is the stronger of the two.

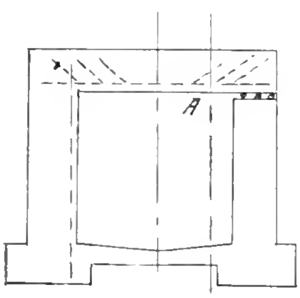

Fig 11.

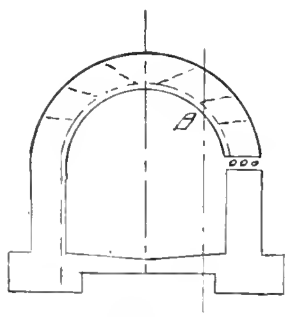

Fig. 12.

Fig. 11 shows a flat top culvert of usual design, consisting of a concrete beam, reinforced with steel tension members embedded near the lower edge, and shearing members arranged diagonally near the ends, supported on reinforced concrete abutments with the bed of the stream paved with concrete.

It is an easy matter to determine the proportions of such a beam required to carry a given load, the beam being a comparatively simple structure from a mathematical standpoint.

Fig. 12 represents an arch having the same span and height of opening and reinforced in a similar manner and with the same thickness of material at any point in the span.

A comparison of the two designs, the properly designed beam culvert of Fig. 11, and the arch culvert derived from it in Fig. 12, shows that the arch culvert is far the stronger and more efficient design, although by no means a properly designed arch.

Assume both beam and arch supported on rollers, so as to be absolutely free from all horizontal forces and unable to offer any resistance to horizontal thrusts. Now, with the same loading on the two structures, the bending moments at any given point of the span are the same for both. Thus the bending moment at A, of the beam is the sum of the moments of all forces to the right of that point. The same is true of the bending moment at the point B, of the arch, since all the forces are vertical and equal in both structures. The bending moment is balanced by the moment of resistance of the section, which is greater in the arch at every point except the crown, where it becomes equal to that at the middle of the beam. At any vertical section other than the crown, the compression is slightly greater in the arch than in the beam, but the tension and shear are less, and at no point of the arch is the compression greater than at its crown, which, like the middle of the beam, is the weakest point in the structure, neglecting shear. In shear the arch has a very decided advantage over the beam, as the section is very much increased at the region of maximum shear. We have, then, the remarkable deduction that a very badly designed arch, not even capable of resisting horizontal thrusts, is as strong as a properly designed beam, having the same section and reinforcement.

If we take both structures under practical conditions, all pressure back of the abutments tends to weaken the beam culvert, by increasing the compressive stresses in the upper fibres of the beam.

No provision can be successfully made in the beam for contraction or expansion.

In the case of the arch, all pressure back of the abutments adds to the strength of the structure, since it sets up moments counter to those produced by the vertical loads, thus tending to reduce the bending moments at the weakest sections. Every inch of upward curvature in a beam culvert increases its strength.

Design of Arch Culverts.—The variations in the design of arch culverts have considerable effect on the cost and efficiency. To combine the least cost with the greatest efficiency, the following conditions should be considered:

(1) The amount of masonry.

(2) Simplicity in the work of construction, forms, etc.

(3) The design of the wing walls.

(4) The design of the junction of the wing walls with the head walls.

(5) The safety and permanency of the structure.

These conditions are more or less antagonistic to each other, but to obtain the best results in design a proper proportion must be reached between the opposing conditions

Arch culverts differ only in size from ordinary arches except that the invert is frequently paved.

A common method of connecting the wings to the abutments is to make an angle of fifteen to thirty degrees away from the axis of the arch and to build them up with the usual batter and thickness. The angle of the wings may be determined by the natural conditions, such as rate of stream, ice conditions and material back of wings.

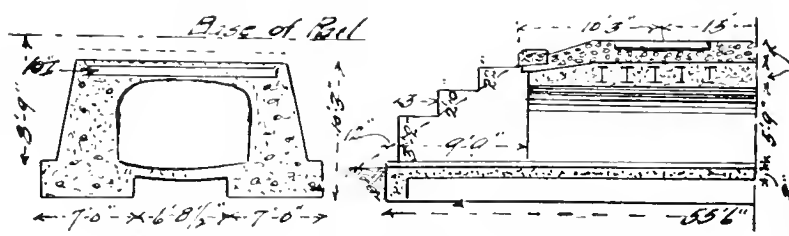

Fig. 13.—Embedded I-Beam Culvert.

To give the best entrance to the culvert for the water and ice, the wings should be carried up to the springing line of the arch flush with the inside face of the abutment and with the same batter. This leaves an entrance to the culvert perfectly smooth, and without corners in which ice or timber might block.

For small concrete arches, plain, from five to fifteen feet in span, they are generally semi-circular arches. For twenty to thirty feet, segmental arches offer some advantages; for the same length of intrados a little wider span is given, the area of the waterway is a little greater, for the same length of span there is a little less masonry. The segmental arch, on the contrary, requires ten to twenty-five per cent. greater thickness of arch ring and abutments.

Trautwine gives the following formula for the depth of keystone:

$$\text{Depth of key in feet} = \frac{2\sqrt{\text{radius} + \text{half span}}}{4} + .2 \text{ feet.}$$

This is for cut stone. For concrete the result should be increased by one-eighth.

Rankine's rule for crown thickness is:

$$\text{For single spans} — 2\sqrt{.12 \text{ radius}}$$

The crown thickness may also be found approximately by first determining the approximate crown thrust. This may be found by obtaining the centre bending moments for all loads, as for a beam, and dividing by the rise. The proper value for crown thrust is that one producing equilibrium about the point of rupture.

Trautwine's rule for determining the thickness of abutments for arches, in feet, at the springing line, for any abutment, the height of which does not exceed one and one-half times the thickness at the base is: The required

$$\text{thickness} = \frac{\text{radius in feet}}{5} + \frac{\text{rise in feet}}{10} + \text{or} - 2 \text{ feet.}$$

The radius used is that of a circle passing through the two springing lines and the crown, on the soffit.

This formula is applicable to a semi-circular, segmental, or elliptical arch. This thickness is given to resist the thrust on the wall, arising from the earth pressure of the embankment of any height, over and around the wall.

Where the earth only extends a few feet above the top of the arch, it is evidently safe to consider the half arch, with its abutment and weight above, as the equivalent of a vertical faced wall of the height of the embankment, and find the thickness of the wall to insure stability, as in retaining walls, or using the thickness followed in practice, that is, from two-fifths to one-half the height. Any greater height of embankment would probably not require any greater thickness of abutment wall. The great stability of the wall, resulting from increase of weight of material above, would balance the increased thrust.

A more extended discussion is impossible on account of the very involved character of such a discussion.

The following method of designing semi-circular arches of reinforced concrete, for spans up to fifty feet and with not more than ten feet of fill over crown is suggested by Dan. B. Luten:

$$\text{Crown thickness} = \frac{\text{span}}{30} + \frac{1}{3}.$$

The outer to be drawn with the centre one-tenth of the span below the centre of the inner circle. The back of the abutments tangent to the outer circle and battered one in four.

The square inches of steel required to reinforce one edge of the arch for one foot in width to be $\frac{HL}{400{,}000C}$.

Where H is the height of the opening in feet.
C is crown thickness in inches.
L is the live load in pounds that can be concentrated in single track, over half the span.

Reinforcing of Culverts.—These remarks will apply chiefly to the semi-circular arch culvert, as they are practically the only culverts built without reinforcing of any kind.

Anyone at all familiar with the condition of the arch culverts along our railroads is aware of the only too common occurrence of cracked concrete culverts.

The most frequent cause of failure is the unequal settlement of the foundations under the two ends of the structure, causing ugly, disfiguring cracks at right angles to its longitudinal axis and, indeed, often noticed extending across the intradosal face of the arch. Similar cracks often occur in the invert. Another type of crack much in evidence is one running longitudinally along the centre line of the invert where the arch usually has the least thickness, indicating unequal settlement of the sidewall foundations.

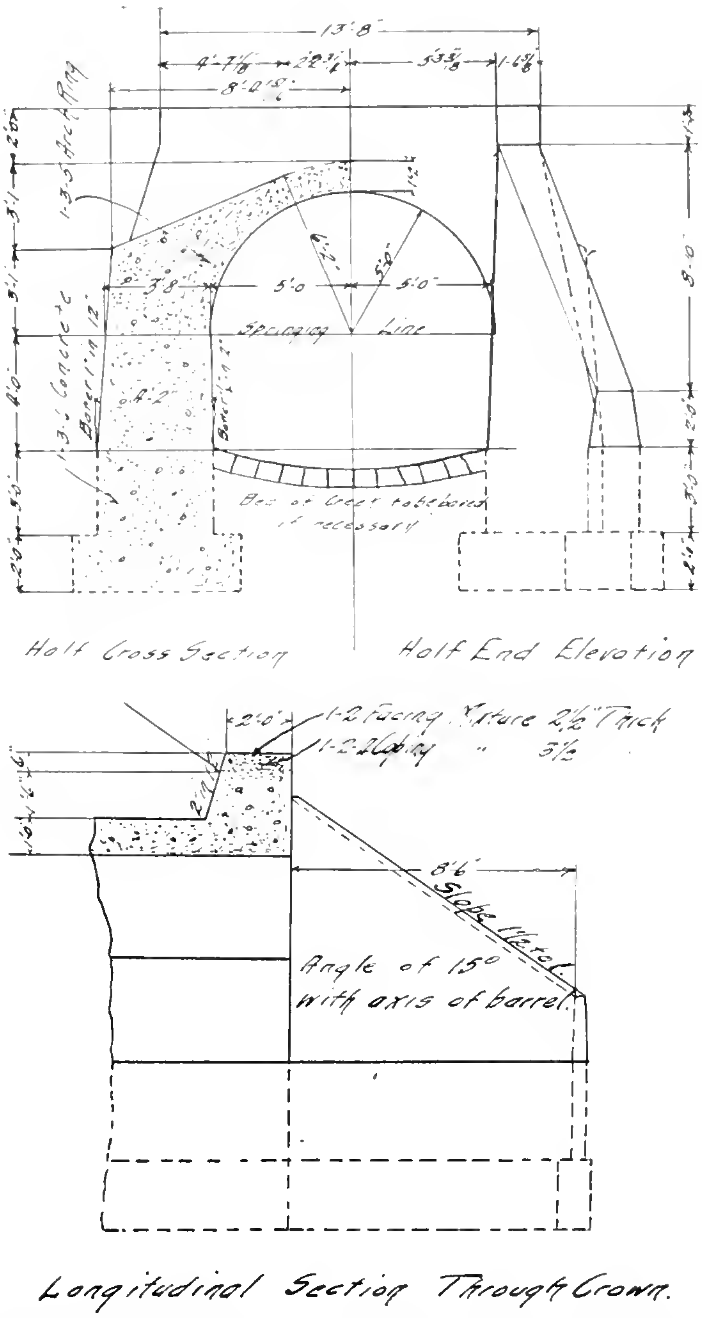

Fig. 14.—Standard (N. T. Ry.) Semi-circular Arch, 10-Foot Span.

Contraction and expansion from changes of temperature, as well as shrinkage stresses, have also been known to have caused cracks in concrete culverts, but these causes of failure are not so common as unequally yielding foundations.

If the culvert is properly reinforced, such conditions as those described above do not occur because the culvert will act as a monolith. The culvert will be capable of beam action and cracks will not appear so readily as in a plain concrete structure, thus far greater durability is assured.

Such a culvert will stand up under more severe conditions imposed by traffic and nature than one not reinforced, and if both were subjected to the same test the reinforced structure would remain intact for a much longer period of time.

Semi-circular arch culverts are in very common use in Canada, without reinforcing. They are used almost entirely

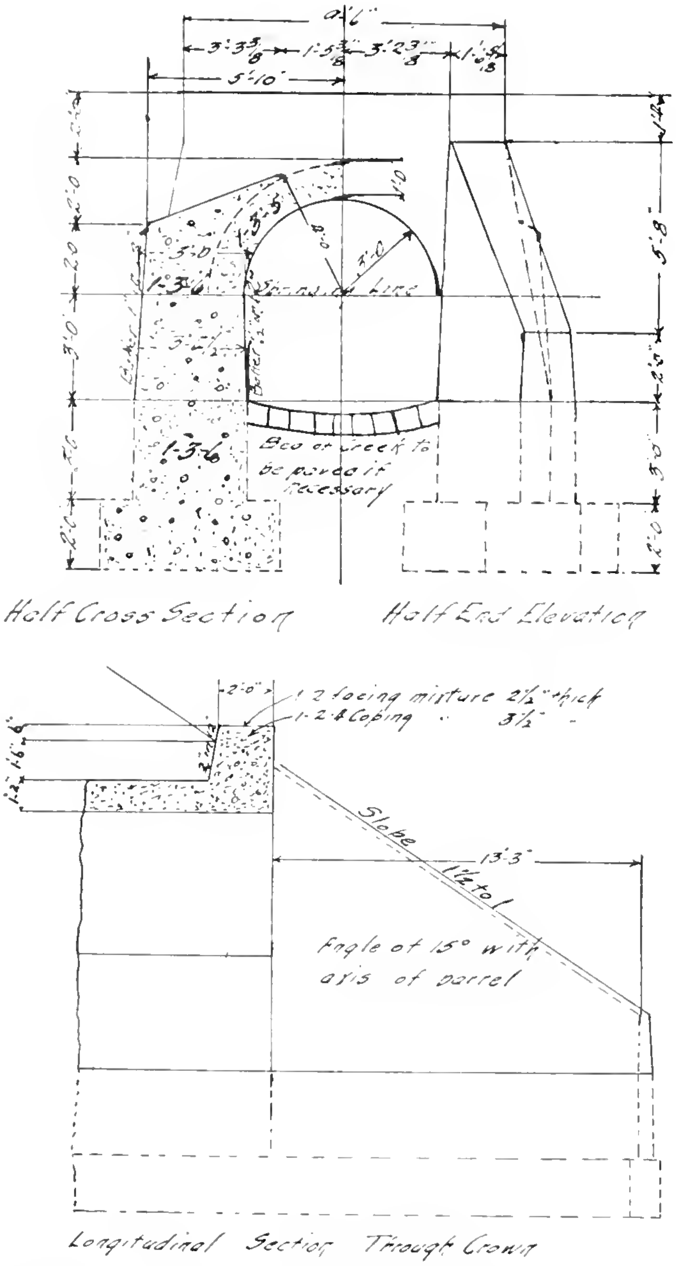

Fig. 15.—Standard (N. T. Ry.) Semi-circular Arch, 6-Foot Span.

by the National Transcontinental Railway and a good example of their abuse is shown there. The standard designs for ten-foot and six-foot spans are shown in Figs. 14 and 15. These culverts are put in, in the majority of cases, without any reinforcing whatever and with foundation conditions far from ideal. Piling is driven, but in a great many cases there is such a large body of poor clay material overlying the solid stratum beneath, that the piling receives very little lateral support, and so, when the fill is made and the pressure comes on the back of the abutments the piling gives away laterally causing longitudinal cracks in the arch. This condition may be prevented by putting in a solid floor of concrete, reinforced diagonally with twenty-pound rails, so as to form a grillage. This enables the culvert to withstand the lateral pressure and the uneven settlement, if it is not too pronounced. With the arch reinforced as well the culvert is practically insured against failure.

The character of the failures in these culverts is well shown in a report compiled by Mr. C. R. Young, B.A.Sc., on a number of the culverts in District "B" of the National Transcontinental Railway. This report shows that about seventy-one per cent. of the culverts on the report show cracks.

The only conclusion that can be arrived at from a view of Mr. Young's report is that all culverts of greater span than five feet should be reinforced, and that provision should be made for expansion joints in those of long barrel.

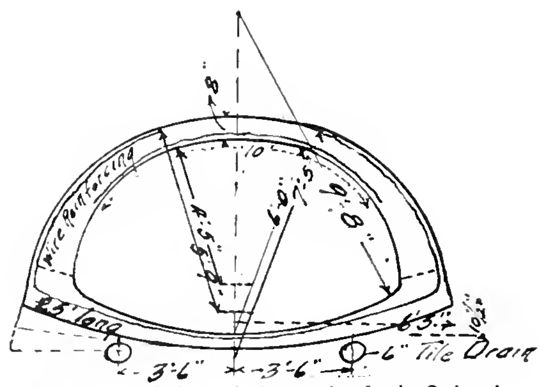

Fig. 16.—Reinforced Concrete Arch Culvert.

Below is given a description of a reinforced concrete arch culvert built at Kalamazoo, Michigan. This is shown in section in Fig. 16.

The culvert is one thousand and eighty feet in length, with a clear width of nine feet ten inches and clear height of six feet. Its grade is from 0.4 to 0.5 per cent. The masonry is entirely concrete, composed of sand, gravel and Portland cement in the general proportions of about one part of Portland cement to six parts of sand and gravel. Actually the upper arch was made with a little stronger mixture and the lower arch a little weaker. Anywhere there was likely to be a little extra pressure a richer mixture was used, under street crossings and where the underlying soil was particularly treacherous.

For reinforcing, a woven steel wire was used. The members of this fabric extending around the culvert were No. 11 steel wire and two layers of the fabric were used, making a total length of wire surrounding the culvert of 175 feet per linear foot. The dotted lines in the figure show changes in the shape of the bearing portion of the concrete, according to the earth on which the culvert is laid. Under parts of the culvert, resting on quicksand two lines of tile drains are laid under the invert to remove the excess water. When drained, it became firm and a good foundation. Before backfilling, interior and exterior of the arch surface were well brushed with neat cement grout.

Costs of Culvert Construction.—Eighteen-foot, semi-circular arch.

The culvert was built under a trestle sixty-five feet high before the trestle was filled in.

The foundation being such that piling was necessary, the railway company drove piling to support a concrete foundation two feet thick and a concrete paving twenty inches thick. The barrel of the culvert was one hundred and forty feet long, but no expansion joints were provided. Cracks developed later, about fifty feet apart, due to the lack of provision for expansion.

The contractors were provided with a large quantity of quarry spalls which had to be crushed by hand. The stone was shipped in drop bottom cars and dumped into bins built on the ground under the trestle. The sand was shipped in ordinary coal cars and dumped into bins. The mixing boards were placed on the surface of the ground and wheelbarrow runways were built up as the work progressed.

The cost of 1,900 cubic yards of concrete in the culvert was as follows, per cubic yard:

1.01 bbls. of Portland cement	$2.26
0.56 cu. yds. of sand @ 60c.	.32
Loading and breaking stone	.25
Lumber, centres, cement house and hardware	.64
Hauling materials	.04
Mixing and placing concrete	1.17
Carpenter work	.19
Foreman (100 days @ $2.50)	.13
Superintendent (100 days @ $5.50)	.29
	$5.29

Only 19 yards per day of concrete were placed, with a gang of 21 negroes @ $1.10 per day. The item for superintendence is high.

Cost of concrete pipes, previously described in this article. The cost of molding the four-foot concrete pipes is estimated as follows:—

Two per cent. of $40 for forms	$ .80
Assuming that a single set of forms can be used only fifty times before being replaced.	
1.1 cu. yds. stone and screenings @ $1.85	2.04
0.8 bbl. of cement @ $2.10	1.68
10 hours' labor @ 28c.	2.80
	$7.32

This gives a cost of $1.83 per linear foot of pipe, of $7 per cubic yard of concrete.

The cost of transporting and installing concrete pipes, on account of greater weight and a greater number of pieces, would probably be very nearly double that for cast iron pipe. However, it is evident that the cost of a concrete pipe culvert in place would be but a small fraction of the cost of cast iron pipe culvert of the same diameter, if the haul is only a moderate distance.

SAVING OUR FORESTS.

"Constant progress in forest conservation" is the keynote of the fourteenth annual report of the Canadian Forestry Association, which has just been issued from the office of the secretary, Mr. James Lawler, Canadian Building, Ottawa. The report, which contains all the addresses made by the prominent forestry experts, legislators and officials at the convention held in Victoria, B.C., is replete with the latest views of the most advanced minds in this line of national public activity. The great strides forward of the Federal and Provincial Governments, two of whom passed far-reaching legislation within the year, unusual progress of the science of forest protection among lumbermen, and the numerous changes in the Canadian Forestry Association itself, all indicate most clearly that the country is rapidly taking up the issue and making for more adequate protection of the great forest heritage. Copies of the Canadian Forestry Association report are to be had free, from Mr. Lawler, on application.

AUTOMATIC SPRINKLERS AND HOTEL FIRES.

The question of fires in hotels in the United States is receiving a great deal of attention just now, and many publications are taking up this hazard not only with respect to loss of the building, but to the lives endangered nightly. The average fire occurrence in hotels during 1912 was one to every thirty-three hours, and during 1913 so far the hotel fire rate has been one every thirty hours. It is stated that eighty-five per cent. of the fires occur between six o'clock p.m. and six a.m.; almost fifty per cent. between midnight and three a.m.; twenty-five per cent. between three a.m. and six a.m., and fifteen per cent. between 9 p.m. and midnight. Hotel fires, it says, were more frequent in 1912 than any of the preceding five years, and so far the increase for 1913 has kept up. The statement is also made that for a period of five years the property loss is estimated at more than $25,000,000, with heavy loss of life.

CANADIAN FORESTRY ASSOCIATION.

The fifteenth annual convention of the Association will be held in Winnipeg, July 7th, 8th and 9th, 1913.

This meeting should be of vital interest to all Canadians who are interested in the conservation of Canada's natural forest resources. Canada's forest area is about 800,000,000 acres, containing some six hundred billion board feet of merchantable timber, worth in the neighborhood of ten billion dollars. But Canadians are cutting this timber at a rate of about 100 board feet per acre, or eight billion board feet per year; the fire loss is estimated to be 950 board feet per acre per annum, which means that these fires are destroying young growth, forest litter and soil fertility on hundreds of thousands of acres That there is a crisis coming is apparent to all—when the forests which for a century men have thought inexhaustible are going to be greatly depleted.

This emergency must be prepared for by stopping the waste in logging, milling and utilization, the destruction of timber by insects and fungus, and protecting the forests from fire. At present Canada spends much less than one cent. per acre per annum on the forest lands under management, and only a fraction of this absolute forest area is growing trees as it might be, the rest being comparatively unproductive. How can Canadians stop the losses, arrest the waste? There is but one answer. Public opinion, public interest, and public conscience are the only forces that will ever make for progress. At the convention a number of practical papers will be read and discussed of problems relating to the great central part of Canada. These will include that of protection and perpetuation of the forests of Western Ontario, and of northern Manitoba, Saskatchewan and Alberta; the best methods of handling prairie forest reserves, and the possibilities of the same in supplying timber, fence posts, poles and cordwood for the settlers; the need of getting under timber the sand lands, which will never produce any other profitable crop but trees, and the rate of growth in the central parts of Canada as a basis for deciding the possibility of economical forestry under these conditions. These will be accompanied by the discussion of the value of forests as windbreaks, sources of stream supply, and as cover for insectivorous birds. Farm forestry, shelter belts to protect buildings and orchards, and the use of hedges will be discussed, as will also the dangers from insects and how these may be dealt with.

COAST TO COAST.

Victoria, B.C.—If plans which a joint committee of the Victoria and Saanich councils are considering are carried out, a magnificent highway along Shelbourne St. to Mount Douglas Park will be constructed. The thoroughfare undoubtedly would be one of the best in the city, and by connecting the city with one of the finest spots in this section would prove an attractive addition to the already numerous beauty spots of which the city and adjoining territory boast. Plans of the proposed improvement have been under preparation for some time and were submitted at a joint meeting of represeutatives of the two councils. These plans show a roadway leading from Bay Street out to and around Mount Douglas, the entire length being approximately three miles. To fully improve this roadway by constructing sidewalks, boulevards, pave an eighteen-foot roadway on either side with a double tramway line in the centre would, it is estimated, cost in the neighborhood of $240,000. To construct only the pavement portion at present would cost approximately $150,000. The city has for some time been contemplating improvements to the Mount Douglas Park. The location is remarkable for its natural beauty and the magnificence of the view to be obtained therefrom. With a thoroughfare such as is suggested Shelbourne Street would be made the connecting link between the city and the park, and the attractions for visitors would be greatly increased. To raise the necessary funds the city and Saanich would have to take the money from general revenue or submit by-laws to their respective ratepayers. But until it is ascertained to just what extent the Government is prepared to go, the financial aspect of the matter will be allowed to stand.

Winnipeg, Man.—The city of Winnipeg has under consideration the expenditure of $14,000,000 towards bringing a supply of 25,000,000 gallons of water per day from Shoal Lake. The estimate is based upon two pipe lines, the first of which would require four years in building. The construction of the second, requiring a time of like duration, would be proceeded with upon completion of the first and would be, generally speaking, an auxiliary line. A gravity system will be used. City Engineer Ruttan submitted an alternative estimate on a combined gravity and pumping system which would cost in the neighborhood of $11,500,000 for construction, but would entail an annual expenditure for maintenance exceeding the gravity system alone by approximately $168,000.

Quebec, Que.—A new electric water-leak alarm is being installed on ocean vessels. It includes a series of small iron boxes screwed at several different heights to the bulkhead of each compartment. Each box has an electric device connected to a convenient indicator-board, which is fitted with small glow-lamps of different colors, and is in circuit with an electric bell. As water reaches the lowest iron box, electrical contact is made, the lamp corresponding to the lowest level lights up, and the bell rings until switched off. The lamp remains lighted as the water rises to the second box, switching the current to the second lamp, or until the receding water is below the lowest contact, breaking the circuit.

Ottawa, Ont.—The final report of the Bradbury committee on the pollution of navigable streams was tabled by the the chairman, the member for Selkirk, on June 2. The report recommends that the government arrange, during the recess, for a conference of representatives of each of the provinces, of the International Waterways Commission and the chairman, Mr. Bradbury, to discuss the whole problem "with a view to overcoming local difficulties and agreeing upon some form of remedial legislation which could be passed concurrently by the Dominion government and the provincial legislatures." The committee also recommends that it be re-appointed at an early period, next session, with a view to carrying to completion the work now begun. The report states that Dr. Hodgetts, of the Commission on Conservation, has been asked, while in England this summer, to inquire as to the latest methods of sewage disposal in the old country, and to obtain furthur information as to sewage and water conditions.

Toronto, Ont.—The work of opening up tne northern territory by the construction of good roads goes on apace. J. F. Whitson, the man who is spending the $5,000,000 granted for the development of New Ontario, points out his progress in a recent report to Hon. W. H. Hearst, minister of lands, forests and mines. Gangs of several hundred men are scattered through the north laying out highways. Great progress is being made, especially in the Rainy River district. "Six camps on road construction have already been established in the Rainy River country employing 80 men, and within the next week or two, 100 to 125 men will be at work in this district," says Mr. Whitson. "By the end of June this number will be doubled." A very large section of land, which is badly in need of additional roads, will be opened up for settlement this year. Road making in Rainy River is very easy compared with other districts. Roads can be made at a reasonable cost as a result of the fires which swept over the country in 1894 and three years ago. A few camps will be started soon in Thunder Bay. Four camps have already been established in Sudbury, and a large force of men is at work. Work in Nipissing is well under way with about 100 men employed. In Timiskaming a number of camps have been started between Englehart and Matheson, and between Matheson and Cochrane.

Montreal, Que.—W. G. Ross, president of the Harbor Commissioners, and M. P. Fennell, secretary of the Board, left Montreal last week to visit the numerous lake ports, where they will go carefully into the grain handling facilities on the Great Lakes. The party will visit Fort William, Port Arthur, Duluth, Tiffin, Port McNicoll and other ports where grain is handled in large quantities. Messrs. Ross and Fennell will also interview the larger grain exporters of Western Canada with a view to having them ship their grain through Canadian ports and especially through the port of Montreal, in preference to the American ports which are now enjoying a large part of the Canadian business. It is expected that as a result of this trip, a large portion of the business now going through American ports will be diverted to Canadian channels, as the only reason local officials can give for this business going to the United States is that the people of the West are not familiar with the facilities which the Canadian ports offer.

Moose Jaw, Sask.—Official announcement was made recently by Hon. Robert Rogers, Minister of Public Works at Ottawa, that the Government had decided to erect two interior storage terminal elevators at Moose Jaw and Saskatoon, to have a capacity of three to four million bushels each and to cost in the neighborhood of a million dollars. The locations for the elevators for Alberta have not yet been decided upon but in all probability the first will be at Calgary. In addition to these interior storage elevators the Government has decided to erect a big transfer elevator on the Pacific coast, which will be owned and operated by the Government in order to handle the grain business which it is expected will flow west by the Pacific when the Panama Canal is opened. A Government-owned terminal elevator of large capacity will also be built at Port Nelson to handle the wheat

which will go north by the Hudson Bay route and this will be ready by the time the line reaches the seaboard. There has been provided in the supplementary estimates four million dollars so that work can be proceeded with at once. Orders have already been given to the Grain Commission, under whose supervision the new elevators will be built, to proceed at once with work on the Moose Jaw and Saskatoon elevators. Both these cities have offered free sites and it is likely the offers will be accepted. The Commission will select the sites at once. The new elevators will be thoroughly modern in every respect, will have full inspection equipment and also hospital equipment for the drying of grains. They will have a capacity of three to four million bushels and will cost in the neighborhood of a million each. As soon as locations are settled in Alberta, work will be started there also. The commission will, it is expected, visit the Coast this summer and make arrangements for the new Pacific Coast elevators. The building of these elevators, it is believed, will do much to solve the difficulties of the annual blockade and transportation problem which faces the western farmer yearly. Hon. Robert Rogers has been particularly interested in this question and has given a great deal of attention to the subject and that the Government is going ahead with the scheme on a large scale is due to the efforts of the Minister of Public Works.

St. Catharines, Ont.—With an expenditure of $50,000,000 planned for the next five years in the deepening of the Welland Canal, there will be an activity in the counties through which this waterway passes that will in some respects rival the work on the big canal across the Isthmus of Panama. Tenders are being called for the construction of the first sections of the work, beginning at the Lake Ontario end. The route to be followed has been settled definitely. It is to follow the Valley of Ten Mile Creek from Lake Ontario, crossing the present canal below lock No. 11 at the level which now exists there, the rise having been effected by three isolated locks with suitable pondage areas intervening. This level is carried through to the foot of the escapement below Thorold, which is overcome by three locks in flight and a single lock on the upper level, in the town of Thorold. Beyond Thorold the level of low water in Lake Erie will be held to Port Colborne, the present canal route being generally followed except between Port Robinson and Welland River. It is proposed to utilize the Welland River and at a point near Humberstone where the present sharp bend will be done away with by a cut-off. The guard lock will be built in this cut-off and will be utilized to protect the canal from the high water of Lake Erie. How great an improvement the new canal will be over the old may be gauged from the fact that instead of 27 locks, as at present, there will be but seven. The scheme is to build the locks 800 feet long by 80 feet wide, with capacity for 30-foot draft, though the canal will not at present be built with a draft of that amount. The reason of this is that the Soo has not yet the 30-foot draft. When it has the Welland will be deepened, but the same locks used. One of the questions that had to be met in planning the new canal was how the Welland River would be crossed by the canal at the town of Welland. On this point Hon. Mr. Cochrane stated to the House that the engineers recommend turning the river into the canal. The minister expressed the opinion that to do this would mean a saving of money and the towns would be helped out, too, by bringing the water supply from the lake. There will be no final dedecision, it is understood, until the towns have been heard from. These towns are Welland, Thorold, Merritton and St. Catharines. The conference to be held with them by the Government will settle the proportionate part of the cost which each of these municipalities should pay to secure fresh water from Lake Erie in the construction of the large pipe line contemplated.

Montreal, Que.—City Engineer Janin has submitted his report to the Board of Control on the measures necessary for the improvement of conditions in Montreal's street car service. This marks the first step toward the betterment of conditions. Mr. Janin's report contains the following important suggestions: The elimination of all unnecessary stops; the placing of switchmen at every important junction point; teaching passengers to have their fares ready; the installation of larger and clearer signs on cars; the relief of congestion in the rear part of cars; the prohibition of the hauling of freight in day time; better supervision of traffic at junction points; doing away with delays at the central office; the prevention of "short-turning" of cars at the option of the conductor; the installation of autobus lines to supplement the tram-cars. Mr. Janin, in his report, has made no recommendations which will entail any large expenditure either by the Tramways Company or the city, and his report cannot be taken as a final solution of the street car problem.

PERSONAL.

D. ROSS, B.A.Sc., is assistant to Mr. Malm, electrical and traction engineer, Toronto Railway Company.

MR. J. E. RITCHIE, B.A.Sc., has accepted a position with the Toronto Iron Works, Toronto, as designing engineer.

CHARLES H. CLAPP, of the Canadian Geological Survey will become a member of the School of Mines faculty at the University of Arizona at the beginning of the next year.

MR. H. H. COUZENS, the new manager of the Toronto Hydro-Electric System, arrived from England last week, but will not take actual charge of the system till July 1st.

MR. L. W. RUNDLETT, at present city commissioner of Moose Jaw, Sask., has been appointed city engineer. This position will be in conjunction with that of city commissioner.

MR. NORMAN K. HAY has been appointed city engineer of Sydney, N.S., to succeed Mr. Campbell. Mr. Hay has been construction engineer with the Dominion Iron and Steel Company.

MESSRS. P. W. ST. GEORGE, J. A. JAMIESON and F. A. BARBOUR have been appointed by the city council of Montreal to report on the nature of the site selected for the filtration plant.

T. KENNARD THOMSON, consulting engineer, of New York City, was in Toronto on Friday last. He attended the commencement ceremonies of the University in Convocation Hall and received the degree of Doctor of Science (Honoris Causa).

S. A. WOOKEY, H. M. STEVEN and V. H. EMERY are directors of the Dominion Mineral Exploration Syndicate, with main offices in Kingston, Ont. Mr. Wookey is field engineer. All three are graduates in mining engineering of the University of Toronto.

HON. THOMAS TAYLOR, Minister of Public Works for the province of British Columbia, has been appointed to represent the Government of British Columbia at the annual meeting of the International Good Roads Congress, which commences June 23 in London, Eng.

MR. JOHN SPROAT, for 35 years road superintendent of Delta, has retired from that position. At a recent banquet which Premier McBride attended Mr. S. A. Fletcher, govern-

ment agent, pointed out the fact that during his long career Mr. Sproat had built and located 800 miles of road, 300 miles of trails, and 300 bridges.

OBITUARY.

MR. JOHN BRECKENRIDGE died at Calgary, Alta., at the age of 52 years. Deceased was born in Ayrshire, Scotland, in 1861, and removed to Peterborough, Ont., in 1867, where he received his education. He was one of the best known and most successful contractors in Canada, having had charge of many important undertakings, notably the C.P.R. irrigation system in that province, which took five years to complete. His firm has also had charge of the C.N.R. construction from Edmonton, Alta., west through Yellowhead Pass to Port Mann. In addition he was connected with many large industrial, mining and other enterprises.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—The Twelfth Annual Meeting to be held in Canada during July and August. Opening day of the Toronto Session, Thursday, August 7th. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

THE INTERNATIONAL ENGINEERING CONGRESS.—Convention will be held in San Francisco in connection with the International Exposition, 1915.

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held at Chicago, Ill., Feb. 16-20, 1914. Secretary, E. E. Kraus, Harrison Bld., Philadelphia, Pa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—176 Mansfield Avenue, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St., Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, A. B. Lambe, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Muckleston; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 534 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSIOCATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase, Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Edmund Burke; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Bedford McNeill; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. J. B. Porter, H. E. T. Haultain and W. N. Miller and Messrs. H. W. Claudet, S. S. Fowler, R. W. Leonard and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE. —Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

TECHNOLOGY CLUB OF LOWER CANADA.—President, F. E. Came; Secretary-Treasurer, E. B. Evans. Meets twice yearly.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

METHODS OF RAPID SAND FILTRATION

GENERAL DESCRIPTION OF SYSTEM — COAGULATING CHEMICALS FOR CLARIFYING RAW WATER—OPERATING DEVICES—COST OF CONSTRUCTION AND MAINTENANCE*

By GEORGE A. JOHNSON, M. Am. Soc. C.E.

RAPID sand filtration first attracted attention as a method for purifying public water supplies in 1885, when a rapid filter plant was built to treat the supply of Somerville, N.J. Since that time this method has come into use in more than 350 cities in different parts of the world and supplies a total daily demand of considerably over 700,000,000 gallons. The largest plant of this type is installed at Cincinnati, Ohio, and has a daily capacity of 112,000,000 gallons. Others are located at Columbus, Ohio, capacity 30,000,000 gallons daily; Hackensack, N.J., capacity 24,000,000 gallons; Harrisburg, Pa., capacity 20,000,000 gallons; Little Falls, N.J., capacity 32,000,000 gallons; Louisville, Ky., capacity 36,000,000 gallons; Toledo, Ohio, capacity 39,000,000 gallons; and New Orleans, La., capacity 40,000,000 gallons. Among the larger rapid filter plants under construction in 1911, were those at Minneapolis, Minn., daily capacity 39,000,000 gallons, and at Grand Rapids, Mich., daily capacity 16,000,000 gallons.

Of the three score rapid filter plants in foreign countries the largest is that at Alexandria, Egypt, capacity 12,000,000 gallons daily. Similar works of even greater capacity are under construction at Kyoto, Japan, and at Cairo, Egypt.

The essential differences between rapid sand filters and slow sand filters are as follows: In the rapid sand filters, the filter units are much smaller; the sand grains comprising the filter bed are much coarser; a coagulant is always used in preparing the raw water for final filtration; the rate of filtration is in round numbers forty times that ordinarily used in slow sand filters; and the whole filter bed, when dirty, is cleaned in the tank itself by forcing water upward through the sand instead of scraping off the surface layers as in slow sand filters.

Up to 1902 rapid sand filters were of more or less uniform design. They were contained in wooden or steel tanks of comparatively small diameter, and the more economical concrete construction had not as yet been attempted. At the commencement of the classic investigations into this process of water purification, conducted at Louisville, Ky., under George W. Fuller, in 1895-1898, even the process itself had not proved its usefulness in the purification of large volumes of water. Provisions for adequate preparatory treatment of the raw water were rarely made, and the whole subject of the suitable design and operation of such works was but little understood.

The need of adjusting the design of rapid filter plants to meet local requirements began to be fully realized when the plant at Little Falls, N.J., was built in 1902 for the East Jersey Water Company. In this plant suitable provision was made for the accurate application of the coagulating chemical (sulphate of aluminum) to the raw water. A basin of adequate size was provided in which coagulation and sedimentation of the raw water could take place. The filter tanks themselves were built of concrete, for the first time, and were rectangular in plan. Improved facilities were installed for agitating the sand layer with compressed air during washing. Neat operating tables, from which all valves could be operated and motors started and stopped by hydraulic power, took the place of the less neat and convenient wheel stands. With the Little Falls plant the modern ideas of proper design for rapid filter plants began to be realized, and its construction marked a most important epoch in municipal water filtration.

Nearly all rapid filter plants are now built of concrete, although wooden and steel tanks are still used for small installations. The filter tanks are ordinarily built monolithic, and embedded in the floor of the tanks is the underdraining system, composed of perforated pipes or strainer cups, designed to permit the filtered water to pass out without allowing sand to escape and to permit an even distribution of water throughout the sand layer when the filter is being washed. Over the strainer system a shallow layer of coarse sand or gravel is placed, and on this rests the sand layer which forms the filter proper.

When the raw water has been sufficiently clarified by coagulation and sedimentation it is passed on to the surface of the filter, over which water ordinarily stands to a depth of several feet, and allowed to pass downward through the bed at a rate of 100,000,000 to 120,000,000 gallons an acre daily, such rates being automatically controlled by special devices. This corresponds to a rate of 2,310 to 2,760 gallons a day on 1 square foot of filtering surface.

The water applied to the filter always contains a considerable amount of coagulated matter, such as mud, vegetable stain, and bacteria, which is retained at or near the surface of the bed. As operation is continued the frictional resistance in the sand layer increases to a point where it is necessary to close the filter for washing. At such times the water standing over the bed is drained down to the level of the overflow gutters, which are located a foot or more above the sand layer, and filtered water is then forced upward through

* Extracted from United States Geological Survey Report, 1913, "The Purification of Public Water Supplies."

the filter, being evenly distributed by means of the strainer system. The material which has accumulated on the top of the sand is thus washed out, and the dirty wash water overflows into the gutters, thence to pass to the sewer. Such a washing operation ordinarily consumes about 10 minutes from the time the filter is closed down until it is again thrown into service.

The rapid filters just described are the type more commonly used: they are known as "gravity" filters and are contained in open tanks.

There is another type, known as "pressure" filters. Such filters are contained in closed steel shells. This type of filter is more extensively employed for household and industrial use, and in some places it is found to be more economical and convenient than the gravity filter. The largest municipal plants of the pressure type are located at Davenport, Iowa, capacity 9,000,000 gallons daily, and at San Diego, Cal., capacity 5,000,000 gallons daily.

Coagulating Chemicals.—The chemicals most commonly used for the coagulation of water are compounds of aluminum and iron, and of these potash alum sulphate of alumina, alumino-ferric, and sulphate of iron are the most extensively employed.

The manufacture of alum is of great antiquity, and for many centuries this chemical has been used in far eastern countries for coagulating water as an aid to clarification. The manufacture of aluminum sulphate from bauxite and alum clay is of more recent origin. The process of making alumino-ferric from bauxite was patented by P. and F. M. Spence in 1875. The sulphate of iron used in water coagulation is for the most part a by-product of iron and steel industries.

The choice between the different coagulating chemicals is properly based on their efficiency as coagulants, and this refers directly to the percentage of available aluminum or iron which they contain. Potash alum, sulphate of aluminum, and alumino-ferric cost about 1 cent a pound; sulphate of iron costs about half a cent a pound. In this country sulphates of aluminum and iron are the most widely employed in water purification, but at the waterworks at Tokyo, Japan, potash alum is used. Sulphate of aluminum is the coagulant in the works at Alexandria, Egypt, and also in practically all rapid filter plants in Europe, India, and Egypt, except at the waterworks at Calcutta, India, where alumino-ferric is used.

In composition these chemicals show considerable variation, but they may be bought on a basis of a guaranteed percentage of available alumina or iron oxides. The essential feature is that the chemical shall be basic, that is, shall contain more aluminum or iron than the equivalent of the sulphate radicle present. The approximate composition of these chemicals now on the market is as follows:

Approximate Percentage Composition of Coagulating Chemicals.

Constituent.	Pure potash alum	Sulphate of aluminum	Alumino-ferric	Sulphate of iron
Matter insoluble in water	.....	0.30	0.06	0.50
Alumina (Al_2O_3)	10.77	17.00	14.26	.....
Iron oxides (Fe_2O_3 and FeO)	.....	.25	.60	57.50
Potash (K_2O)	9.93	.....	.....	.....
Sulphur trioxide (SO_3)	33.76	38.70	35.81	28.80
Water (H_2O)	45.54	43.75	49.27	13.20

When potash alum, sulphate of aluminum, or alumino-ferric are applied to a turbid water the chemical is rapidly decomposed. The strong sulphate radicle of the chemical displaces the weak carbonate or bicarbonate radicle in the water, and an equivalent amount of carbon dioxide is liberated. The white, insoluble, and gelatinous aluminum hydrate that is formed absorbs the dissolved color and envelops and brings together into comparatively large aggregates the mud and the bacteria in the water. These flocks of coagulated matter are removed with comparative speed by subsidence.

Generally speaking, the application of these coagulating chemicals to a water will bring about a slight increase in the amount of incrustants in the water and a decrease in temporary hardness. The total hardness of the water—that is, the sum of the temporary hardness and the incrustants expressed in terms chemically equivalent—will remain unchanged. The increase in incrustants has some significance as regards corrosion of uncoated iron and incrustation in boilers; but, practically speaking, these are factors of comparatively little importance in view of the relatively small amounts of the coagulating chemical ordinarily employed.

Most surface waters naturally contain more than sufficient carbonate and bicarbonate radicles to make possible complete decomposition of the chemical which is applied for coagulation. In some waters, however, the natural alkalinity is so low, particularly at times of floods, that this is not true, and for such waters it is necessary to make up the deficiency by applying soda ash or lime water before the coagulant is added.

Sulphate of iron, known commercially as copperas, is obtained in two grades, namely, the ordinary commercial by-product from iron and steel manufacturing, and the higher-grade sugar copperas manufactured by a vacuum crystallizing process.

The use of copperas in water purification introduces more complicated features than alum compounds, chiefly for the reason that lime is required for the precipitation of the iron. When added to a natural water the copperas is decomposed somewhat like alum except that the formation of the hydrate of iron takes place very slowly. By adding lime in the form of limewater or milk of lime rapid formation of insoluble iron hydrates is induced. In general terms it may be stated that to obtain satisfactory results from the use of lime and iron as coagulants it is necessary to make use of sufficient lime to neutralize and precipitate the iron. The use of too little lime results in poor coagulation, caused by the incomplete precipitation of the iron, some of which is usually left in solution and appears in the effluent of the filters. The use of too much lime results in the formation of lime incrustants, which deposit in the air and strainer systems and cause much trouble through clogging.

Water treated with lime and iron will show an increase in permanent hardness, as compared with the effect of the use of compounds of aluminum. In general the aluminum salts are considered more satisfactory as coagulants: they remove color from water more rapidly and completely and make it possible to obtain by filtration a more brilliant water than do iron rails.

Devices for Application of Coagulants.—No department in a filtration plant is more important than that wherein the coagulating chemicals are applied to the water. To obtain satisfactory results from the plant as a whole and the filters in particular, it is necessary that the application of the coagulating chemicals be at all times under strict and accurate control and be adapted to the quality of the water to be filtered. Material variation in the dose of the chemical applied to the water or in the quality of the water means overdosing or underdosing. The former results in a waste of the chemical and sometimes in undecomposed coagulant in the filtered water, and the latter results in incomplete coagulation and impaired efficiency. Owing to the high rates of filtration used in rapid filters undercoagulated water will

leave the filter in a less purified state and will possess an undesirable turbidity. The filter will run longer without washing because of the slower accumulation of coagulated material, but the efficiency will be poor.

The different types of device for the control of the application of chemicals are very numerous and are all designed to be as nearly automatic as possible. The appliances which have given the best results are those wherein provision is made for the application of the solution under a practically constant head through an orifice which can be adjusted at will. The depth of solution over this orifice should not be less than 6 inches, and this depth may be maintained by allowing slightly more of the solution to be delivered into the orifice tank than is allowed to escape through the orifice, the excess being discharged back into the main solution tank through an overflow, or by means of a float valve. The overflow is by all odds the more reliable.

The sulphates of iron and aluminum have a corrosive action on almost all metals, and it has been found advisable to make all of the metal parts which come in contact with the solutions of lead, copper, or special bronze. It is sometimes found advantageous to use hard rubber piping, valves, and orifices, but the cost may preclude the use of such material. Rubber piping and valves are easily broken, and the cost of replacement may prove no inconsiderable item. Generally speaking, however, the decision as to the kind of metal to use depends on the relative cost of the cheaper iron and its correspondingly higher cost for repairs and replacements and the ease with which repairs can be made, and the higher first cost of more expensive materials and the lower cost for upkeep.

Improved Devices for Filter Operations.—As already pointed out, it was not until 1902 that marked improvement was made in the direction of making easier the manipulation of valves and other apparatus, which has so much to do with the successful and economical operation of a rapid-filter plant. Until that time all valves, without exception, were opened and closed by hand. When a filter required washing, it was necessary to close the influent and the effluent valves, and to warm up the steam wash-water pump preparatory to supplying wash water to the filter. Now the operator moves a lever at an operating table, and by means of hydraulic cylinders valves are opened or closed with practically no manual effort or loss of time. Electrically driven wash-water pumps have largely supplanted the steam pumps, and the operator starts and stops this pump merely by pressing a button at the same operating table. Air compressors, which supply air to the filters during washing for the purpose of agitating the sand layer, have in most large plants taken the place of the steam-driven rotary agitators, and these compressors are also started and stopped by pressing a button on the operating table.

As time savers these various improvements more than pay for themselves, and the neat appearance of the newer plants is a vast improvement over the older plants with their multitude of wheel stands.

Filter Washing.—When a rapid filter has become so clogged with coagulated matter that the normal rate of filtration can no longer be maintained, the influent valve is closed and the water standing over the sand layer is drawn down to the top of the wash-water gutters. The effluent valve is then closed and the wash-water pump is started. This pump forces filtered water up through the sand layer until it is freed of practically all of the accumulated matter. The pump is then stopped, the influent and the effluent valves are opened, and filtration is resumed. In some places the filters are washed by water delivered under the requisite pressure from an elevated tank.

During the process of washing a filter it is the practice in the majority of the newer rapid-filter plants to break up the sand layer with compressed air before turning in the wash water in order to facilitate and accelerate the cleaning of the sand grains. In some places, as at Cincinnati, Ohio, and New Orleans, La., no provision is made for agitating the sand layer during washing other than such agitation as induced by the upward flow of wash water. In the older plants, and in some of those recently built, wherein the filter tanks are circular in plan, the sand is agitated during washing by means of rake teeth attached to arms which revolve, driving the teeth through the sand.

When washing a filter the rate of application of wash water must not be too low, and on the other hand it must not be too high, or sand will be carried from the bed with the wash water. Ordinarily the best rate of application of wash water is about 6 to 8 gallons to the square foot a minute, which corresponds to a vertical rise of about 1 foot a minute.

This is equivalent to three to four times the rate of filtration. When wash water is driven upward through a filter bed of normal construction at these rates, the sand layer will rise from 3 to 5 inches, but practically no sand will escape from the bed except during the early stages of operation of a new filter.

Before the modern appliances for facilitating the labor of operation were installed it was not unusual for periods out of service for washing as great as 30 minutes to be recorded, and frequently the time consumed was even longer. In the more recent filters this period rarely exceeds 10 minutes from the time the effluent valve is closed until it is again opened.

Control of Rate of Filtration.—If uniform rates of filtration are required for the successful operation of slow sand filters, then uniform rates are of even greater importance in rapid sand filters. The reason for this is plain. Slow sand filters are operated at actual rates of about 3,000,000 gallons an acre daily; rapid filters are operated at rates from 30 to 40 times as high as this. A sudden fluctuation in these higher rates means a correspondingly greater shock, and impaired efficiency naturally follows.

Although within certain limits there is no particular objection to the rate of filtration in a rapid filter gradually diminishing, a sudden increase in rate will cause an almost immediate deterioration in the appearance and hygienic quality of the effluent. If the rate increases or decreases slowly and steadily no harm may result, but should the rate increase abruptly, even as much as 20 per cent., the effect of the change will usually be apparent from the inferior appearance of the filtered water.

Therefore, to maintain a constant rate of filtration in the rapid filter, automatic controllers are always used. There are many such devices, but the object of all it to maintain a uniform rate of discharge from the filter independent of the head on the outlet pipe on which the controller is located. Although many improvements in these devices have been made in recent years, the best of them subject the filter to fluctuations in rate of at least 10 per cent. Furthermore, on account of the tendency of floats and butterfly valves in these controllers to stick, such fluctuations may occur within a very few seconds. In drawing up specifications for controllers it is frequently stated that such variations from the normal rate shall not exceed 2 per cent., but this requirement is rarely if ever met. Nevertheless the controllers do practically the work required of them, and without them a rapid filter would be unable to maintain a high standard of efficiency.

Cost of Construction of Rapid Sand Filters.—It is almost as difficult to state the comparative cost of construction of rapid sand filters as of slow sand filters. Local conditions largely govern, and it is possible and feasible to build some plants much more cheaply than others, and at the same time obtain plants which will prove as efficient as those which are more complete and ornate. A summary of the more prominent installations and their cost indicates that unless some unusual features are encountered, as in the filters at Little Falls, N.J., where the flow throughout is entirely by gravity, compelling the use of relatively expensive deep structures, or the abnormally large preliminary settling basins at Cincinnati, the cost of a rapid-filter plant, exclusive of high-lift and low-lift pumping equipment, will be about $12,000 for each million gallons daily capacity. On the basis that the water consumption is 125 gallons per capita daily, the first cost to each consumer of such a plant would be about $1.50. At 6 per cent., the interest charges on such an investment would be 9 cents per capita annually.

The above-mentioned fixed charge on the cost of construction of rapid-filter plants is materially lower than that of slow sand filter plants, as would be expected. As a general proposition, it is not usually thought necessary to build large sedimentation reservoirs in which the raw water may be first settled before the coagulating chemical is applied and the water is allowed to flow into relatively small coagulating basins. Where turbid waters are to be purified by slow sand filter plants, large sedimentation reservoirs must be provided or preliminary filters made a part of the system in order to remove the bulk of suspended matter, which would speedily clog the slow sand filters and make the cost of operation of such filters unnecessarily high. The preliminary treatment factor has a great deal to do with increasing the first cost of construction of slow sand filter plants, and, furthermore, the much greater area of filtering surface required for these filters also explains why it costs so much more to build them. It must be borne in mind, however, that all figures of cost herein given are not to be considered as strictly comparable, but only as examples of what has actually been obtained in the construction in this country of filters of the slow sand and the rapid types.

Cost of Operation and Maintenance of Rapid Sand Filters.

Range of Cost.—In the cost of operation of rapid sand filter plants the size of the plant and the quality of the raw water are the main controlling features. Privately owned works are usually operated at lower cost than are those owned by municipalities. As a general proposition, however, the total cost of operation and maintenance of rapid sand filter plants, exclusive of the interest on investment and pumping charges, ranges in this country from about $3 to $5 for each million gallons of filtered water. For some plants the cost is even less than $3, and for others it is in excess of $5 for each million gallons. The following examples will show the cost of operation of several plants in this country.

The Little Falls plant is filtering about 30,000,000 gallons daily. The charge for superintendent and labor includes the salaries of the superintendent, one filter foreman, four filter attendants, an analyst, and a boy. On a basis of a yield of 30,000,000 gallons daily, the cost of operation for each million gallons of water filtered is as follows:

Cost per Million Gallons of Water Filtered at Little Falls, N.J.

Labor	$0.80
Coagulant	1.43
Heat	.35
Power	.22
	$2.80

No itemized costs of operation of the plant at Binghamton, N.Y., are available, but it is understood that the total cost is about $6 for each million gallons of water filtered.

During 1910 the Harrisburg filters were operated at an average rate of slightly over 9,000,000 gallons a day. The cost of operation for each million gallons during 1910 was $5.31 and was divided up as follows.

Cost per Million Gallons of Water Filtered at Harrisburg, Pa., in 1910.

Labor	$2.52
Coagulant	1.06
Supplies	.28
Repairs	.38
Coal	.63
Oil and waste	.07
Laboratory	.37
	$5.31

During the year 1910, which was a representative year, the average yield of the Cincinnati rapid-filter plant was 49,000,000 gallons daily. The total cost of operation and maintenance was $4.19 for each million gallons of water filtered, the charge being made up as follows:

Cost per Million Gallons of Water Filtered at Cincinnati, Ohio, in 1910.

Supervision and attendance	$1.98
Coagulant	1.93
Repairs	.28
	$4.19

Total Cost of Rapid Sand Filtration.—It has been stated above that the average cost of rapid sand filter plants is about $12,000 for each million gallons daily capacity, which cost will include the necessary filter building, the filters, and the coagulating and filtered-water basins. At 6 per cent. this cost corresponds to a fixed charge of about $2 for each million gallons. The addition to this charge of a fairly average figure for operation and maintenance makes the total cost of filtered water by the rapid sand filter system, exclusive of pumping charges, about $6 for each million gallons. On the basis of 125 gallons per capita daily consumption, the total cost of water filtration will be, according to these figures, about 27 cents per capita per annum. This estimate is approximate and is subject to considerable variation according to the conditions in various places. It is obvious that the larger the filter plant the lower will be the cost of operation per million gallons; and also that where waters require a great deal of coagulating chemical the cost of operation will necessarily be increased in proportion.

Efficiency of Filtration.—Slow sand filters will render water clear and practically free from turbidity and will remove a material percentage, probably from 20 to 30 per cent., of the dissolved color in waters stained by decaying vegetable matter. They are not able to treat successfully and economically the very muddy waters of the central western and the southern portions of this country unless such waters are first subjected to long periods of plain sedimentation or to shorter periods if coagulants are used. Rapid sand filters are capable of treating successfully practically all kinds of water, but are particularly applicable to the treatment of waters heavily charged with suspended matter or which are highly colored. The final effluent from such filters will contain practically no residual color or turbidity. Both types of filters will ordinarily remove all but about 1 or 2 per cent. of the bacteria originally present in the raw water.

In the following table are given a few representative samples of the efficiency of slow and rapid sand filters in cutting down the typhoid fever rate in communities where they are used. This is one of the best indices to the bacterial efficiency of filters. In addition to the reduction of typhoid fever effected by filters, it appears to be a fact that the death rate of a community is materially reduced by the substitution of a pure for a polluted water supply. At the International Engineering Congress, held at St. Louis in 1904, Allen Hazen made the following statement:[1]

* * * Where one death from typhoid fever has been avoided by the use of better water, a certain number of deaths, probably two or three, from other causes have been avoided. This seems the clear and logical conclusion from the statistics. It is not easy to explain how the water is connected with the deaths other than those from typhoid fever. It may be that a good water supply, used freely and with confidence, results in a better general tone in the system of the population, and so indirectly to a lower death rate, and that a part of the reduction is represented by diseases having no recognized connection with the quality of the water supply.

Death Rate From Typhoid Fever per 100,000 Population in Cities Using Filters.

A SILICIOUS WOOD PRESERVATIVE.

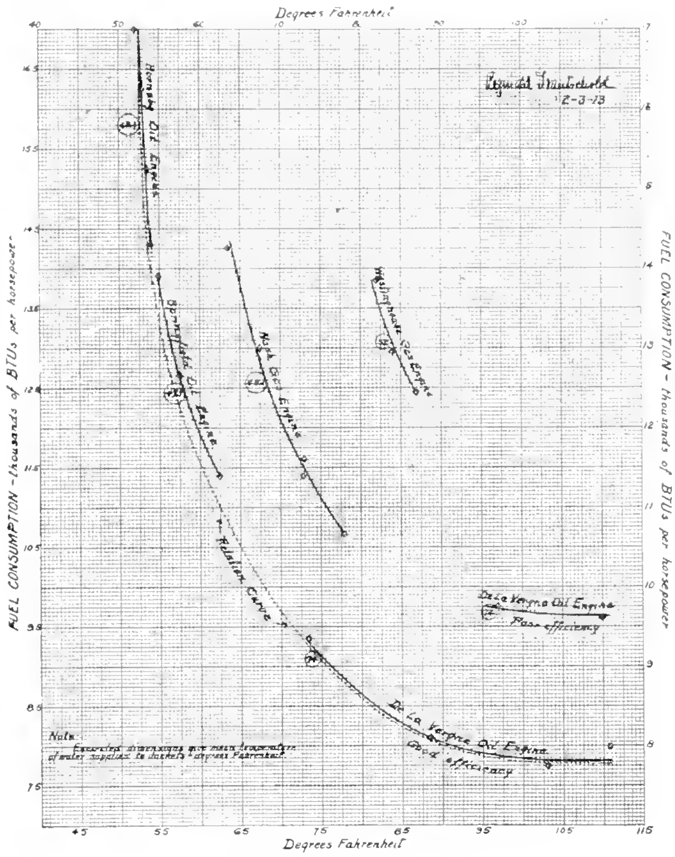
In a new process for the impregnation of timbers with melted paraffin and naphthalene, diatomaceous earth, a silicious material, is ground so fine that ninety-two per cent. passes a two-hundred-mesh screen. This is mixed with the melted paraffin and the naphthalene and timbers immersed in the mixture for four hours. As compared with the twelve to twenty-four hours required in creosoting, this is noteworthy. Furthermore, it is an open vat process. The wood is permeated to the centre and resists the attack of marine borers and decay, besides gaining the resilience. Nails hold better and do not rust, nor does the wood become waterlogged. Hardwoods, like white oak, which resist other treatment, yield to this preservative. The expense is small, for the mixture costs only three cents per pound, and less than two pounds of solution are required for each cubic foot of timber.

When completed, New York's skyscraper, the mammoth fifty-five-story Woolworth Building, will have cost approximately $13,500,000, of which amount $4,500,000 represents the cost of the land, $1,000,000 of foundation excavation, and $8,000,000 for construction.

JACKET WATER TEMPERATURES AND FUEL CONSUMPTION IN INTERNAL COMBUSTION ENGINES.

By Reginald Trautschold, M.E.

The thermal efficiency of internal combustion engines, the proportion of the heat units supplied that are converted into available or useful kinetic energy at the fly wheel—is, and has been, high as compared with that of even the most efficient types of reciprocating steam engines. And one of the main reasons of the recent wide adoption of the former type of engine to service of all kinds lies in the fact that its average efficiency, as the engine is to-day manufactured, shows considerable improvement over that of similar engines built but ten or fifteen years ago. This increased efficiency has been obtained through the use of more suitable mixtures in the combustion chamber, better regulation, improved design, and proportions, etc., etc., until at the present time



TEMPERATURE RANGE OF JACKET WATER

CHART I

internal combustion engines operating on crude and the heavier oils have occasionally developed a thermal efficiency of about 35 per cent. Such progress is very gratifying and has helped in the wide introduction of internal combustion engines, but even now many such engines are being operated below their best efficiency from lack of general and proper knowledge of the requirements and conditions governing efficiency. Particularly is this so in the question of jacket water temperatures—water jacketing being generally resorted to in stationary engine practice—and a study of this question is, therefore, of particular interest.

In considering the effect of jacket water temperatures upon fuel consumption, two main points naturally present themselves, 1st, the amount of heat that the jacket water should absorb—i.e., its temperature range, for most satis-

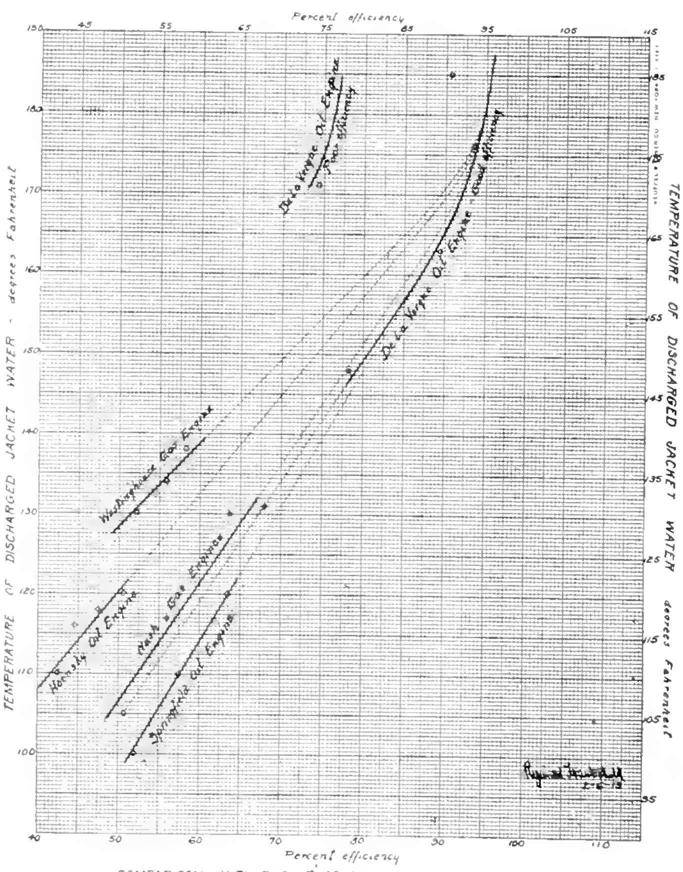
factory operation; and 2nd, the temperature at which the water should be discharged from the jackets. The first consideration governs the amount of jacket water that should be used, as the available temperature range of jacket water supply is inconsequential, when the intense heat of the gases at the moment of ignition is taken into consideration—a point of importance when the jacket water is cooled on discharge from the jackets and used over again, a practice that is nearly universal. The second consideration is but a logical deduction from the first, but it is, nevertheless, upon this point that the economic consumption of fuel or thermal efficiency of the engine largely depends.

Engines operating under all degrees of efficiency must be considered before any conservative and reliable rule can be advanced to govern the supply and temperature of the jacket water that will assure the converting of the greatest proportion of the heat units supplied by the fuel into useful energy. Hence, the data given in Table I does not do justice to the possibilities of the various types of engines mentioned, nor does it properly indicate their relative efficiencies, but is merely a record of the jacket water temperatures of engines operating under various degrees of efficiency.

Table I.

Type of Engine	Fuel and Heating Value	Consumption of Fuel per Horsepower	Jacket Water Increase Range	Temperatures Discharged Water
Oil Engine "A"	Kerosene	17,000 B.T.U.	52.0 F.	110 F.
	20,000 B.T.U.	16,250	53.0	116
	per pound	15,250	53.5	118
		14,300	54.0	120
Oil Engine "B"	Gasoline	13,900 B.T.U.	55.0 F.	100 F.
	18,000 B.T.U.	12,650	57.5	110
	per pound	11,400	62.5	120
Oil Engine "C"	Fuel Oil	9,250 B.T.U.	73.5 F.	148 F.
	19,000 B.T.U.	8,100	88.5	163
	per pound	7,750	103.0	176
		8,000	111.0	185
		9,750	97.0	171
		9,600	110.0	184
Gas Engine "A"	City Gas	14,250 B.T.U.	63.5 F.	110 F.
	560 B.T.U.	13,000	67.5	117
	per cubic foot	11,600	73.0	127
		11,400	73.0	130
		10,650	78.0	131
Gas Engine "B"	City Gas	13,850 B.T.U.	82.0 F.	130 F.
	560 B.T.U.	12,950	84.0	134
	per cubic foot	12,450	87.0	138

The effects of temperature range of jacket water on the fuel consumption are graphically illustrated by the curves of Fig. I, a chart which clearly indicates two important facts. One, that the relation existing between the range of temperature of jacket water and consumption of fuel, for engines operating on fuels of about the same heating value, follows closely the relationship illustrated by the smooth curve designated "Relation Curve" and that about the same relation exists for engines operating on fuels of any specific heating value. Two, that the temperature of the water supplied to the jackets, within usual limits, has little effect upon the efficiency of the engine as far as fuel consumption is concerned. Considering only the engines operating on fuels of about the same richness or heating value, it is seen that the fuel consumption decreases rapidly with any increase in the temperature range of the jacket water for relatively small values of heat absorption by the jackets and that the rate of fuel consumption continues to decrease with increasing temperature range of jacket water, with gradual retardation, until a temperature range of about 105 degrees Fahrenheit is reached, after which the fuel consumption of the engine remains about constant. During this period of minimum fuel consumption, little or no gain in efficiency is obtained by increasing the temperature of the range of the jacket water, and if increased to such a point that the discharge temperature is too high, a point that will be referred to again, serious generation of steam in the jacket will occur, reducing the efficiency of the jacket and upsetting the rule that increased temperature range of jacket water is conducive to reduced fuel requirements. With unusually cold water supply it is possible, of course, to retain the water in the jackets until a considerable range of temperature takes place, but as previously stated the possible temperature range of the jacket water supply is limited and the possible gain in fuel consumption due to increased temperature range of jacket water is hardly sufficient to warrant running the risk of an interference with the water supply that may counteract the small gain in economy of fuel consumption through increased temperature range of jacket water by a too great increase in the



COMPARISON WITH ENGINE OF 35 % THERMAL EFFICIENCY

CHART II.

temperature range of the jacket water to from 100 to 130 degrees Fahreinheit, depending upon the temperature of the water supplied to the jackets, in ordinary installations of internal combustion engines. Engines operating on fuels of lesser heating value, require a greater range of jacket water temperatures to give the same fuel economy as those operating on fuels running about 18,000 or 20,000 B.T.U. per pound but, as in all cases, the temperature range of the jacket water is limited by the temperature at which it is discharged from the jackets, and this is governed by the generation of steam in the jackets.

About the best thermal efficiency for an internal combustion engine that has yet been attained is 35 per cent., or the delivery of one brake horsepower per 7,250 B.T.U. supplied, and for sake of convenient comparison, such efficiency will be considered as 100 per cent. A comparison of the thermal efficiencies of various engines, as represented by the data of Table I, with that of an engine delivering a horse-

power of useful energy per 7,250 B.T.U. supplied, shows that the temperature at which the jacket water is discharged, has a marked effect upon the efficiency of the engine. This is graphically illustrated in Fig. 2 and, though there appears to be considerable variation in the efficiencies of the various engines when the jacket water is discharged at a relatively low temperature, the curves for the various engines all point to a maximum engine efficiency when the jacket water is discharged at a temperature at 180 degrees to 190 degrees Fahrenheit. Above 180 degrees the improvement in efficiency is very gradual, as it is at this temperature that the generation of steam in the jackets usually begins to become serious. With well designed and proportioned jackets, however, the jacket water may be safely retained in the jackets until a temperature of 190 degrees Fahrenheit is reached, but beyond such temperature it is very questionable whether any appreciable increase in efficiency is attainable.

The temperature of the jacket water supply is of secondary importance, as its only effect upon the efficiency of the engine is that the cooler it is the less jacket water is required—that is, the greater the possible temperature range—but as a temperature range of from 105 to 115 degrees Fahrenheit furnishes the maximum economy in fuel consumption under ordinary conditions, no material benefit is derived by having the jacket water supply cooler than 70 or 75 degrees Fahrenheit, other than reducing the mean velocity of the supply through the jackets. This, in the average case were the water is used over and over, is conducive to additional expense rather than to economy, as cooling facilities have to be greater than when the water is returned to the jackets at a higher temperature.

The operating engineer has discovered that certain benefits are to be derived by discharging the jacket water at higher temperature than was formerly considered good practice for the engine tests from which the data of Table I was collected, cover a period of some ten or fifteen years, the tests in which the jacket water was discharged at a relatively cool temperature, having been made in the late nineties while those tests in which the jacket water was discharged at the higher temperatures being of comparatively recent date—all tests having been made according to good practice at the time they were made, and to ascertain the best efficiencies of the engines rather than as studies of the effect of jacket water temperatures.

MEXICAN PETROLEUM OUTPUT.

The development of Mexico's petroleum industry is shown by the following statistics of output of crude oil in the past six years: 1907, 1,000,000; 1908, 3,481,410; 1909, 2,488,742; 1910, 3,332,807; 1911, 14,051,643; and 1912, 16,500,000 barrels.

The Canadian Pacific Railway Company, who have invited tenders for two 600 ft. high-speed Atlantic liners, have placed an order with Denny, Dumbarton, Scotland, for two auxiliary steamers of 375 ft. length.

The International Road Congress, which will be held this year in London, England, June 23rd to 28th, will bring together the leading men from practically every country identified with highway construction and maintenance. This is the third Congress of the kind to be held, and is the first to be held in an English-speaking country. The first Congress was held in Paris, France, and the second in Brussels, Belgium. These Congresses are held every three years.

PRESERVATION OF RAILROAD CROSS TIES.

In rather extensive experiments carried on by the United States Forest Service in the preservation and use of cross ties, the following results were secured and deductions drawn:—

Zinc chloride is an effective preservative for ties subjected to the severe conditions under which the experimental ties were laid, as a result of which 87 and 92 per cent. respectively of these ties were serviceable after seven and one-half years. A fairly heavy impregnation of zinc chloride is advantageous. Treatments by the Burnett and Wellhouse processes, made at Somerville, with two per cent. zinc chloride solutions and average absorptions of 0.35 and 0.33 pounds of dry salt per cubic foot of wood, resulted in only 45 and 47 per cent. respectively of serviceable ties after seven and one-half years' service. Similar treatments made at Chicago with a 4 per cent. solution and average absorptions of 0.42 and 0.57 pounds of dry salt per cubic foot resulted in 87 and 92 per cent. respectively of serviceable ties after the same length of service.

A light injection of creosote apparently adds to the effectiveness of zinc chloride treatments. The Allardyce treatments, made at Somerville, show 81 per cent. of serviceable ties, while treatments made at the same plant with zinc chloride alone show only 45 per cent. of serviceable ties after seven and one-half years. Beaumont oil in combination with zinc chloride also produced an effective treatment.

Treatment with preservatives will not yield good results unless the ties are sound in the first place and the treating is properly done. This is strikingly shown by the treatments of zinc chloride and English creosote. These ties were probably injured by over-steaming during the treatment.

The experiments seemed to indicate that ties treated with zinc chloride suffered more mechanical wear than untreated ties, and from this it would appear that the zinc chloride treatment weakens the wood. This result was also noticed on the creosoted ties, in one experiment, but in another, on ties which had been treated with about fourteen pounds of creosote per cubic foot, examined two years after placement in track, approximately two per cent. were slightly affected with decay, and about twelve per cent. of those treated with zinc chloride, but on inspection of a number of ties which were more or less split, it was found that the exposed portions of the ties appeared thoroughly sound and well treated, and it seems probable that the greater part of them were slightly affected with decay at time of treatment, and only two ties could be found showing any rail wear, and this was so slight as to be negligible.

In general, however, these experiments, carried on with seven different railroad organizations, show that in many cases the life of ties can be doubled or even trebled by proper treatment, but to secure this result, the ties must receive a first-class treatment of a good preservative and must receive a liberal and not a skimping treatment.

Ties with low decay resistance, such as loblolly pine, hemlock, tamarack and beech, if laid untreated, should not be tie-plated, as they will decay before they will wear out, even without the tie plates, and, this being the case, the tie plates are a useless expense and do not prolong the life of the tie. However, the increased resistance to decay caused by proper treatment makes it highly desirable to protect the ties from deterioration from mechanical sources, and this is particularly true of ties with low crushing strength.

Practically all radium-bearing ores mined in Canada and the United States are sent to Europe for the extraction of the radium.

FOUNDATIONS FOR PITT RIVER BRIDGE.

Features of the Location and Requirements—Special Interim Construction for Continuous Use—Progress to Date.

While Canada seems to be experiencing great prosperity throughout the entire country, nowhere does this development seem to be making such rapid strides as on the Pacific Coast. This is apparent to everyone who will glance at the enormous outlays by the older railroads for betterments and easements, and also by the strenuous efforts of several new roads to complete their lines across the continent in order to participate in this prosperity and development.

The Canadian Pacific Railway is spending enormous sums in double-tracking, flattening out curves, cutting down heavy grades, and building many new bridges of a type sufficient to accommodate its rapidly increasing traffic. One of the biggest, and perhaps the most difficult, pieces of work between the coast and the summit of the Rockies, is the foundation for the Pitt River bridge.

The present bridge, which is a single-track structure, has been in use only approximately six years, and already it is incapable of handling the traffic passing over it. In addition to this, there lies between the western end of this bridge and Westminster Junction the new terminal yards of the Canadian Pacific Railway, upwards of half a mile wide and two and a half miles long. These conditions made it doubly imperative, on the part of the railroad, to construct a new bridge capable of handling the increased traffic.

The Pitt River is tributary to the Fraser, and is subject to the rise and fall of the tide, although no salt water reaches this point. The river itself, which joins the Fraser opposite Port Mann, and about six miles above New Westminster, has a depth of water reaching almost seventy feet in many points. It is about ten miles long and drains a large body of water known as Pitt Lake. The maximum current is approximately three miles an hour, and this is upstream. One peculiarity of the river is that, while the current is still setting upstream, the level of the water in the river begins to fall, the outward flow not taking place until the water level at the bridge site has fallen approximately six inches.

The new bridge, which is to be a double-track one, spans the river at a point about two miles above its confluence with the Fraser, and is approximately 1,750 feet in length between the backs of ballast walls of the east and west abutments.

The work divides itself naturally into two distinct classes: One comprising pier No. 1 and piers No. 6 to 13 inclusive, together with the two abutments, which are being constructed by the use of sheet piling cofferdams; while piers No. 2, 3, 4 and 5 are to be put in by means of large caissons, which will be built on land, launched, floated into exact position and there sunk to the river bottom. Through wells, the sand, which comprises the river bottom at these points, will be excavated; and the caisson will be weighted to force it downward. When a sufficient penetration has been obtained and the soil at this point, as indicated by borings and by the actual excavation, is satisfactory, the bottom of these dredging wells will be sealed under water, and concrete allowed to set, when the caissons will be pumped out and the rest of the pier constructed in the manner similar to the methods obtaining on land.

The depth of water at the site of pier No. 2 is approximately 45 feet; the depth at piers No. 3 and 4, approximately 65 feet; while the depth at pier No. 5 is about 35 feet. The depth of water at the other piers gradually diminishes until reaching the abutments, the sites of which are above ordinary

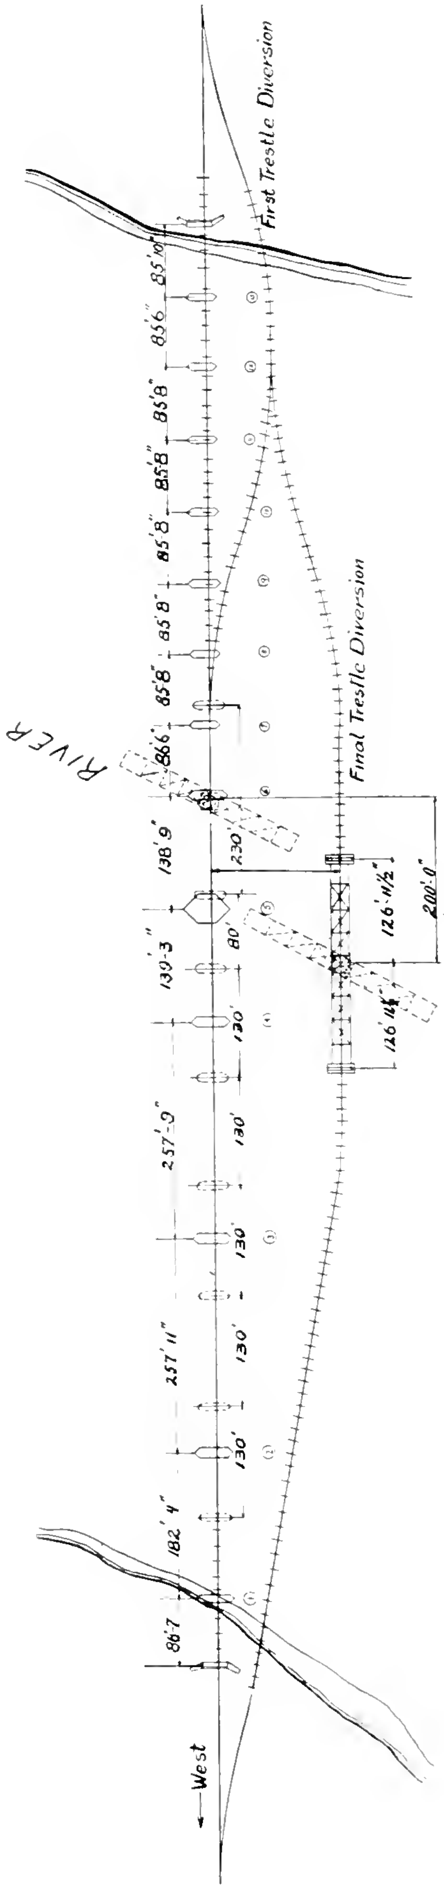


Fig 1.—Layout of C.P.R. Pitt River Bridge, Coquitlam, B.C.

high tide. The river is subject to the annual floods which inundate the banks of the Fraser. At this point on the Pitt, the shores are protected by dykes or levees about 18 feet in height, which is approximating the height of the base of rail of the railway. These annual floods are very irregular in time and occurrence, and also in the elevation to which they rise. There seems to be no possibility of foretelling what the conditions may be, as the snows on the mountains are always sufficient to supply enough water, provided the rise in temperature is sudden and of sufficient duration.

The Foundation Company, Limited, of Montreal, Canada, was called in to do this work, on account of the recognition of the many difficulties anticipated here, and also because this company had successfully handled difficult work of a similar nature in the east for the railway company.

Recognizing the desire for the completion of this work at the earliest possible point of time, operations were begun immediately, no delay for the removal of traffic from the old bridge taking place. The construction of the two abutments and several of the piers was prosecuted while traffic was still operated over the old bridge. At the same time, the railroad company began to construct trestle work across the river, for the purpose of diverting this traffic. The diversion was

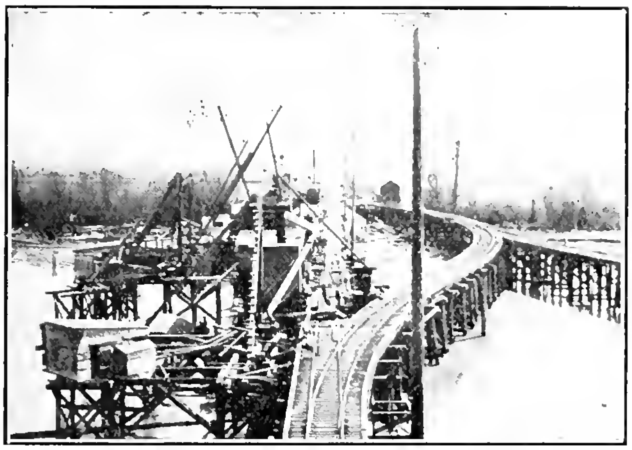

Fig. 2.—C.P.R. Pitt River Bridge, Showing Trestle and Work on Eastern Portion.

a necessity, owing to the fact that two of the old piers had to be demolished, in order to accommodate piers for the new bridge, as well as to shorten the time of construction. This pile trestle is expected to be completed by the end of June. The railroad company is now erecting the truss of the swing span, which was formerly used in the old Red River bridge, where the foundations for a new bridge had been built by The Foundation Company. This swing span for the trestle is being erected on the guard pier, and at right angles to the line of traffic. When this is in operation, the swing span of the old bridge will be floated out of position, and the old pivot pier removed, so that the east rest pier for the new swing may be erected at this point. The west rest pier of the old swing must also be taken out, as the pivot pier of the new bridge will be constructed on its location.

By reference to the accompanying plan, the reader may note the pile trestles built by the railway company to accommodate the diverted traffic, as well as the old piers which had to be removed, and the location of the new piers, with the lengths or dimensions, centre to centre, of the various plate girders and trusses of the new bridge. The work on the new bridge has been pushed forward with all possible despatch; the two abutments and piers No. 12 and 13 having been completed, while piers No. 1, 9, 10 and 11 will be completed early in the month of June. The soil on the west side of the river, where pier No. 1 was constructed, under the old bridge, while traffic was maintained at this point, consists of very compact, rather finely grained sand, rather difficult to

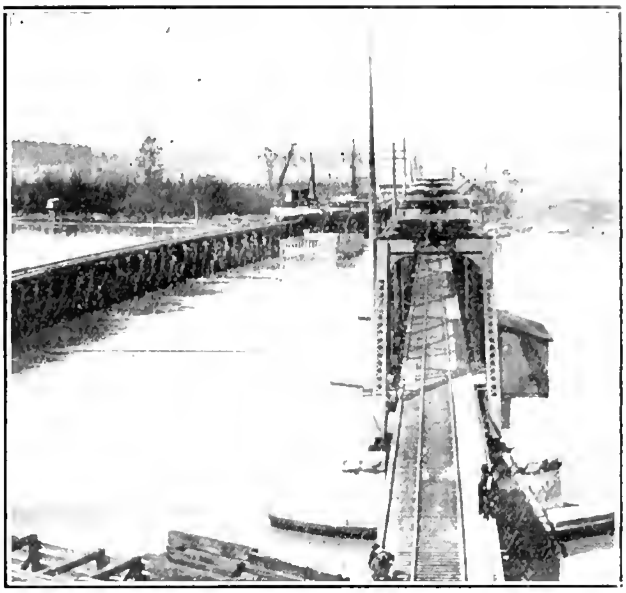

Fig. 3.—C.P.R. Pitt River Bridge, Showing Western Portion of Main Trestle.

handle; while on the eastern bank of the river the soil, which was largely of a clayey silt, contained many pockets of fine, white sand, along with stumps, driftwood, roots and branches of trees, and also layers of dead vegetation, making it, on the whole, a most treacherous class of material. The removal of the stumps loosened up the soil to a considerable depth; the dead wood, which could not be reached by ordinary means, or the presence of which could not be known, shattered some of the sheeting, which had to be pulled and replaced, while the layers of vegetation in this soil permitted the water, when under only a moderate pressure, to penetrate into the excavation rather freely, but all these difficulties either have been or are being successfully overcome.

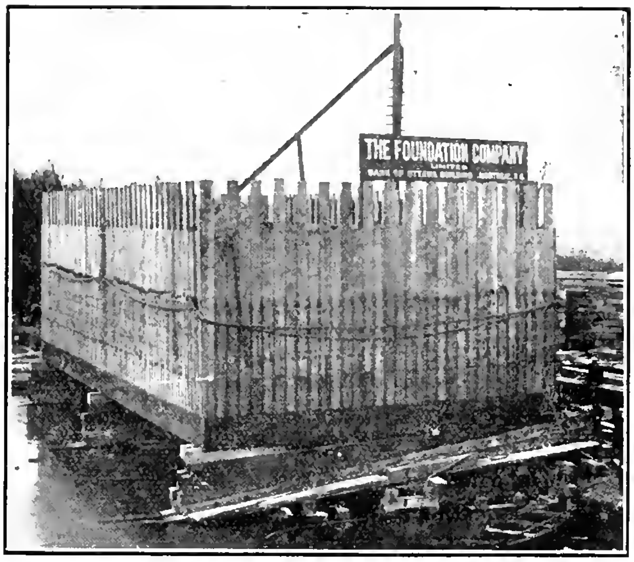

Fig. 4.—C.P.R. Pitt River Bridge Caisson No. 2, Ready for Launching.

The caissons which are to be dredged to proper depth are, roughly, 35 feet wide by 75 feet long, containing two dredging wells about 17 x 20 feet and, when complete, will be over 100 feet high. One of these has already been launched and is ready to be put in position, while the second one is on the launchways and almost ready to be put into the water. These caissons were built to a height of about 12 feet, caulked and otherwise made water-tight, and weighed, when launched, approximately 250 tons, with a draft of 8 feet. Owing to the scour which developed in the river bottom when the old piers were being constructed it was decided that it would be unsafe to place these large piers in position, namely, midway between the old piers, until after traffic was diverted to the pile trestle, so that this part of the work has been confined entirely to the construction of the caissons.

The work is handled by the Vancouver office of The Foundation Company, Limited, under the direction of Mr. J. G. Sullivan, chief engineer, C.P.R.; Mr. H. Rindal, division engineer, and Mr. J. R. Middleton, resident engineer. It is expected that the work will be nearing completion by the end of the year.

GOOD ROADS PROBLEM IN SOUTH VANCOUVER.

With the advent of the automobile two problems were created on the trunk roads in all countries which the various road authorities have since been endeavoring to solve as efficiently and as economically as possible, the abatement of the dust nuisance and the preservation of the surface of the roadway.

The South Vancouver counncil has recently decided upon two steps which, though at first glance do not seem to have any connection with each other, are yet very closely allied. The council has decided to engage the services of a consulting engineer to advise as to the practicability of establishing a municipally-owned gas-making plant on the North Arm of the Fraser River, and they have given a contract to the M. P. Cotton Company to oil five miles of roadways in the municipality at a cost of $175 per mile. The council has also decided to permanently pave Main and Fraser Streets with creosoted wood blocks.

The oiling and the paving propositions have two main objects, the abating of the dust nuisance and the preservation of a good road surface; and, though these two objects would at first appear to have no connection with the proposal to establish a municipally-owned gas-making plant, there is as a matter of fact a very close connection.

Probably in no country in the world are there better trunk roads than those running throughout the length and breadth of the British Isles; and in recent years nearly all of those roads have been treated either with raw coal tar or with some proprietary preparation of coal tar, which, as everyone knows, is a product derived from coal during the process of manufacturing gas.

The method of treatment varies, but whether raw tar is used or the more expensive proprietary preparations, the result of treating a road surface with coal tar is practically the same, a good, solid surface, over which an auto glides with a smooth, even motion, practically dustless, yet impervious to water during wet weather. The only difference is the cost.

Engineers differ in their opinions as to the best method of treating a road surface with coal tar or a preparation of tar. Some assert that the crude or raw tar needs to be refined before using it on the roadways; others declare that the raw tar is by far the best for painting the surface of a roadway, and they are of opinion that better results are obtained from the use of raw tar than from the use of any of the many preparations of tar.

While the road construction engineers are settling the question to their own satisfaction it may be interesting to record the result of an experiment carried out by the municipal engineer to one of the urban authorities on the North Wales coast over a period of five or six years.

The highway between Holyhead and Chester runs through his district, and in addition he has many miles of roadways under his control. The municipal council owns the gas works, and for the past five or six years the engineer has been experimenting with various preparations of tar and with the raw tar as it comes direct from the gas works, for the purpose of treating the roadways under his control; and, as the result of his experiments he has come to the conclusion that the tar direct from the gas works gives better results than any preparation on the market.

The method which the engineer in question has found to give the best results is a very simple and inexpensive one, working out in his case at less than a cent per square yard for the actual spraying and cost of tar after the roadway had been prepared for the treatment.

The first essential for the success of tar spraying is a good, even-surfaced macadamized roadway with a fairly level top: that is to say, with less fall to the sides than would be necessary if the surface was not to be sprayed. After the roadway had been thoroughly rolled the engineer mentioned had the road brushed, thus removing all dust and loose stones and soil. An old water-cart or sprinkler was then taken to the gas works and filled with warm raw tar, and on arrival at the piece of roadway to be treated the tar was sprinkled over the surface in exactly the same way as would be done in sprinkling water to lay the dust, the only difference being that two men followed the sprinkler armed with wide rubber squegees with which they distributed the tar evenly over the surface of the roadway, one-half of which only was treated at once, leaving the other half open to traffic and paths across the tarred half for foot passengers.

Dry weather is the second essential for success in tar-spraying, because two days are necessary to allow the tar to percolate into the roadway. Given those three essentials, a good macadamized surface, dry weather during operations and evenly distributed sprinkling of tar, a road surface is produced which is impervious to water and is practically dustless.

A second sprinkling given a few months later will still further improve the roadway, and with a third sprinkling a surface is produced equal to the most expensive asphalted pavement to be found anywhere.

RAILWAY IMPROVEMENTS IN ROUMANIA.

A bill has been introduced in the Roumanian parliament to authorize the expenditure within the next five years of $80,000,000, for the completion of railway lines now under construction, the improvement of existing lines by double tracking, building of new stations, etc., and the construction of new lines of about 1,000 miles in length, and of a bridge over the Danube.

It is stated that motor cycles are coming into extensive use in the cities and suburban roads of Egypt, the topography of the country being generally favorbale for sport and practical cycle riding. The machines used are almost all of French, Swiss and English make.

METHODS OF DESIGNING THE FLAT SLAB SYSTEM.

By W. G. Ure, B.A.Sc.

In taking up the question of design of flat slab floors it has been found impossible to give any definite and generally accepted solution, for the simple reason that, of all the methods of treating the subject outlined in the following pages, no one can be singled out as an established standard. Different lines of investigation pursued by different men have given different results, and these results lead to widely varying designs when applied to the solution of a definite problem. It is not possible in an article of this length to go fully into these methods of design, and this chapter will therefore be devoted to an attempt to place before the reader the fundamental principles upon which some of the commoner of these methods are based, and to a comparison of the results attained thereby. It must be left largely to the individual reader to use his own judgment and experience in deciding which solution he would prefer to adopt.

In the flat slab system of floor construction we have the three fundamental stresses to provide for, viz., tension, compression, and shear. The tension and compression are due to moment action and it is with regard to their computation that most of the uncertainty exists. The determination of the shearing stresses is comparatively simple and will be considered first.

The shear is of two classes as before noted—punching shear and shear tending to produce diagonal tension. The safe stress for concrete to be used in computing the resistance to punching shear has been placed by the Joint Committee at 120 lbs. per sq. in. The safe stress to which concrete may be submitted in diagonal tension is the same as that which is safe for straight tension or from 40 to 50 lbs. per sq. in. The usual practice in the design of reinforced concrete is not to compute the diagonal tension at all, finding the punching shear only and using such a low permissible stress that the other will be automatically provided for. Let us then assume the safe shearing stress for concrete as 40 lbs. per sq. in. There is a well-known principle that at any point in a beam, the vertical shear, the horizontal shear, the diagonal tension, and the diagonal compression are all equal. Hence by limiting the allowable stress in vertical or punching shear to 40 lbs. per sq. in., we are also at the same time limiting the stress in diagonal tension to the same amount, and we may then not consider the latter in the rest of the design.

In any flat slab design there is a large amount of steel centering at the column and this, of course, may be utilized in the resistance of shear. This steel reinforcement may be stressed in shear up to 10,000 lbs. per sq. in. Then the total resistance to shear is the strength of the concrete at 40 lbs. per sq. in. plus the strength of the steel at 10,000 lbs. per sq. in. It has been shown by experience that practically the same result is obtained if the steel be neglected and the concrete figured at a stress of 80 lbs. per sq. in.

In actual practice it is probably just as easy to compare the shear from first principles. However, a formula may be derived as follows:—

Consider a section around the edge of the column cap, which in general would be the critical section.

Let A be the area of floor in sq. ft. sending load to the column.

a, the area of the column cap in sq. ft.

p, the perimeter of the column cap in inches.

jd, the distance in inches from the centre of compression to the centre of steel.

w, the combined dead and live load per sq. ft. of floor.

v, the intensity of shearing stress per sq. in.

Then the load tending to shear the floor at the edge of the capital is $w\ (A - a)$ lbs.

The area provided to resist the shear is $(p\ .\ jd)$ sq. ins.

Then v equals $\dfrac{w\ (A - a)}{p\ .\ jd}$ lbs. per sq. in.

The required depth of slab should be computed at the edge of the column cap, at the edge of the column shaft proper, and preferably at one or two points in between. Then, by plotting these depths the size and shape of the flare required at the top of the column is obtained. From the equation it will be seen that v may be decreased by an increase of either p or jd.

It frequently happens that the depth of slab is fixed from other considerations, hence in considering the section at the edge of the column cap jd is fixed, and v must be controlled by varying p. The tendency from æsthetic considerations is to fix the width of the cap by the size of the column beneath, and it may happen in an upper story where the columns are small that the width of cap be reduced too much. From a structural point of view the width of the column cap does not depend at all on the size of the column beneath, but only on the load to be carried on the floor above, and this load may be just as great on the top story as on the lower ones. The depth of the column cap will depend on both the size of the column and the floor load.

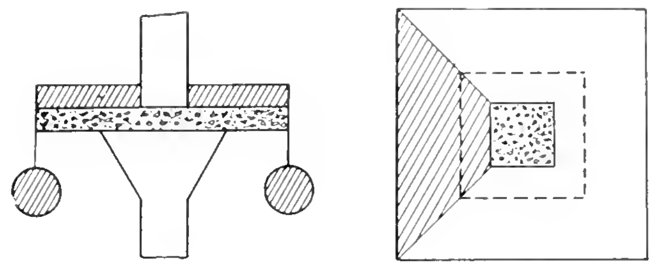

Fig. 1.

In all some eight methods of figuring the moments in the flat slab will be given brief consideration. The first two methods, viz., the "Cantilever Method" and "Turneaure and Maurer's Method," may be grouped together as being based on the principle that the portion of the slab over the column head out to the point of inflection acts as a cantilever, and the rest of the slab acts as a suspended span hanging from the edge of the cantilever.

The Cantilever Method is a simple application of the principles of statics, based on certain preliminary assumptions. The point of inflection is assumed at a distance out from the centre of the column equal to one-fifth of the span. The cantilever portion is then assumed to be a square whose side equals two-fifths of the span. Fig. 1 shows this part of the slab with a uniform load over its surface and a concentrated load equal to the weight of the suspended span hanging from its extremity. It is then a simple matter to compute the moment at any section. Moments should be found about the edge of the column shaft, the edge of the column cap, and preferably at one or two points between. The depths required can be then obtained, and the size of flare found in this way compared with that found by considering the shear.

The suspended span is analyzed by dividing it into strips, as in Fig. 2. Consider two such strips, one $A—B$ running diagonally across the panel, and the other $C—D$

along the side of the panel. Fig. 3 shows the bands of steel and the location of these strips. The figures on the shaded portions indicate the number of bands of steel crossing at that point. Assume that where one band only is present it takes all the load, where two are present each will take half the load, and so on, each band taking its proportionate share of the load. Fig. 3 also shows the way in which these strips will then be loaded, and the bending moment in each can be readily calculated. Having obtained the moments, the depth of slab and amount of reinforcing required is found in the usual manner.

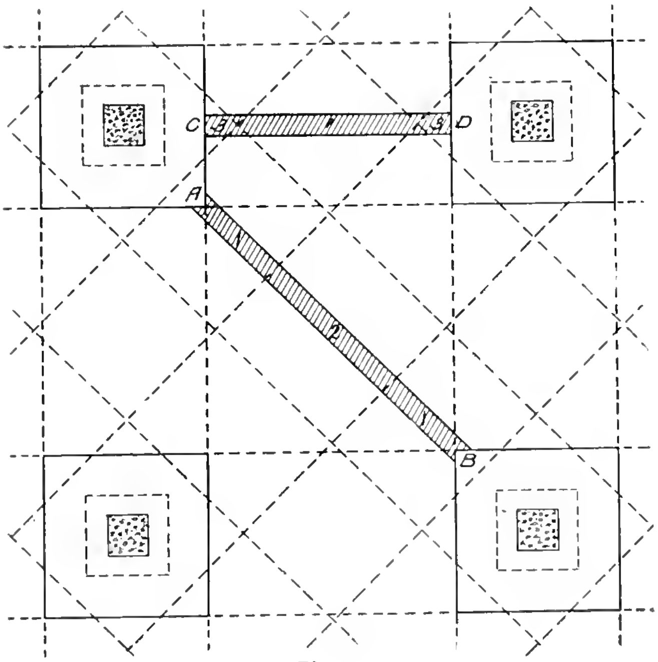

Fig. 2.

There are at least two serious objections to this method. In the first place it depends on the position and form of the line of inflection which is indefinite, and in the second place it takes no account of slab or arch action in the slab itself.

Turneaure and Maurer's Method is a modification of the above. It consists in considering the slab over the column head out to the point of inflection as a flat, circular plate uniformly loaded and supporting the rest of the slab as a concentrated load around its circumference. The radius of the circular plate is taken as the mean of the distances out to the point of inflection in a diagonal direction and in a direction along the side of the panel, the points of inflection being assumed at the fifth points. The determination of the moments is somewhat difficult mathematically, but they may be easily obtained by means of tables or graphs provided. The suspended portion of the slab is solved in a manner exactly similar to that used in the cantilever method. Graphs and tables for the solution of the flat slab by this method are given by Sanford E. Thompson in his paper entitled "The Practical Design of Reinforced Concrete Flat Slabs," published in *The Canadian Engineer* for March 28th and April 4th, 1912.

This method is open to the same objections as the previous one. It gives a thickness of slab approximately 50% in excess of that given by any other method, and this excess thickness, we can safely say, is unnecessary from our knowledge of the behavior of slabs under test loads.

Another Method of analysis is to divide the slab into a number of beam strips, as proposed by Mr. W. H. Ham in the proceedings of the National Association of Cement Users, 1911, page 195. The assumptions which he makes can be readily understood from Fig. 4. The load on the diagonally hatched portion is assumed to be carried by the diagonal beams, one-half being taken by each, and that on the vertically hatched portion by the cross-beams. The loading on diagonal and cross-beams would then be as indicated in the figure. The section required can then be obtained by the usual methods for solving reinforced concrete slabs, using the moment formula for beams fully restrained, partially restrained, or freely supported, as the case may be. The remaining portion of the slab over the column head is solved as a cantilever. The bars in the cross-beams are brought to the top of the slab over the columns. The bars in the diagonal bands run straight through on the bottom, and additional bars are provided at the top of the slab to take up the cantilever moment in the diagonal direction.

While this is, undoubtedly, a safe method of procedure it neglects the effect of arching action in the slab, and thus the result would tend to be unnecessarily heavy. On the other hand, it is simple to apply, uses only established engineering formulae, and the necessary allowance for end and corner panels is readily made.

Another Method is proposed by Louis F. Brayton in the proceedings of the National Association of Cement Users, 1910, page 269. He considers the structure as a slab reinforced in two directions and takes the moment at the centre as $-\frac{Wl}{12}$. Considering the load to be carried one-half each way we get a maximum moment at the centre of $\frac{Wl}{24}$ and double this over the columns. Brayton claims that where the length of the panel is more than one and one-half times the breadth it is conceivable that the slab might not become a warped surface under certain conditions of loading, but that the maximum deflection might be along a line perpendicular to the middle point of the long axis. In such a case the whole load should be assumed going in the direction of the long span. In order to make use of the assumption of two-

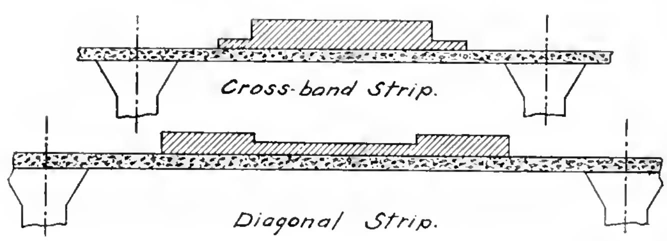

Fig. 3.

way reinforcement, Mr. Brayton assumes the strength of the diagonal bars replaced by its resolved parts parallel to the length and breadth of the panel. The use of such a low moment factor gives a heavy design, but his treatment of the long, narrow slab would seem reasonable.

In his book, C. A. P. Turner refers to Grashof's analysis and a treatise by Dr. Eddy entitled "Theory of the Flexure of a Thin Flat Plate or Ring Loaded Symmetrically About its Centre." However, his method of design appears to be purely empirical. From a series of experiments, such as were described in the writer's article in June 6th issue of this journal, he obtained the formula $\frac{Wl}{50}$ for bending moment. It would appear that his tests were made on isolated panels only, and if this be true he has built up his formula

on insufficient data. His designs are extremely light and seem somewhat daring when compared with designs made by other engineers. In some cases floors built by Mr. Turner have not stood up well under service.

Grashof's Analysis of the "Stresses in an Infinite Flat Plate supported on a Series of Points Dividing it into Rectangular Panels" may be used for the design of flat slabs. The proof is rather intricate but the results are comparatively simple and are given by Mr. Mensch as follows:

Bending moment at centre $\frac{Wl}{52.8}$

Maximum bending moment $\frac{Wl}{26.4}$

Maximum deflection $.0284 \frac{Wl^4}{Et^3}$ in which the value of

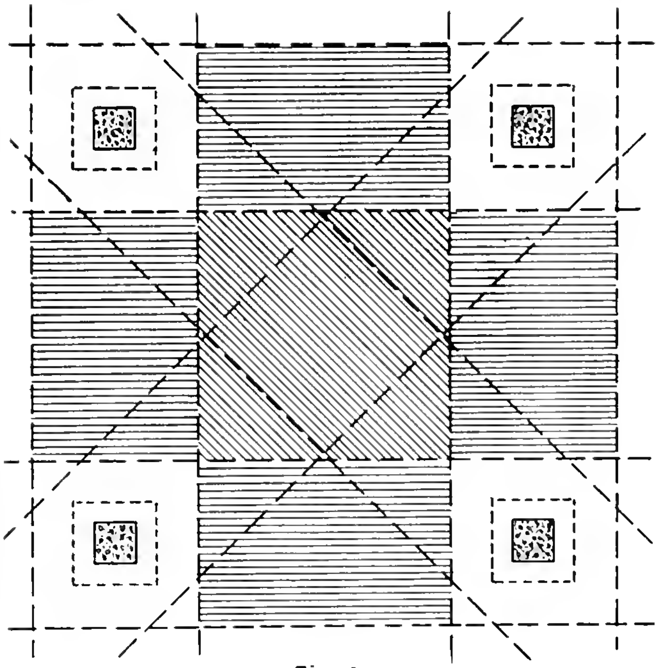

Fig. 4.

Poisson's ratio is taken as one-third. The objection to this method is that Grashof's Analysis is based on the assumption that he is dealing with a square plate of homogeneous material and uniform thickness, in fact the proof is indeterminate for other than a square plate. Actual flat slab floors are seldom exactly square, are not homogeneous throughout, and the flare of the columns, coupled with the fact that more layers of steel are present at some places than at others (changing the position of the centre of tension and thus the effective depth) make the assumption of uniform thickness unfair. Further, the slab can hardly be said to be supported at four points, as it is actually fixed over a considerable area at the corners. In spite of these discrepancies, however, the moment formulae given probably express pretty well the conditions actually existing.

L. J. Mensch describes a method based on the above. He claims that the formula $\frac{Wl}{48}$ for maximum bending moment at the centre of the span may be deduced from Grashof's writings. He then reasons that the same ratio of bending moment between the ideal condition of a continuous beam uniformly loaded, and such beams as designed and loaded in an every-day building, shall also hold good for the girderless floor. This ratio is $\frac{Wl}{24} : \frac{Wl}{10}$ or 1 : 2.4 Then, reducing $\frac{Wl}{48}$ in the same ratio he obtains $\frac{Wl}{20}$ as his working moment formula, and this, he claims, gives a factor of safety of four.

McMillan also obtains his formula from Grashof, but by a different line of reasoning. He quotes two of Grashof's formulae for maximum fibre stress in square plates uniformly loaded as follows:

Supported on two edges $f = \frac{3}{4}\,\frac{W L^2}{T^2}$, and fixed on four points, $f = \frac{W L^2}{4.27\, T^2}$. These values are in the ratio of 3.2 : 1. He then assumes that the ratio of the bending moment in a beam or slab simply supported and uniformly loaded and that in a flat slab will be the same. The formula for the former is $\frac{Wl}{8}$; therefore the corresponding formula for the flat slab is $\frac{1}{3.2} \cdot \frac{Wl}{8}$ or $\frac{Wl}{25.6}$. For convenience the value $\frac{Wl}{25}$ is taken and the slab figured out on this basis.

From this discussion it is evident that the Grashof formulae are unsatisfactory because, if for no other reason, they are capable of too many interpretations. The revised Cleveland building code gives the formula $\frac{Wl}{27}$, and the writer is inclined to believe that the correct value of the moment coefficient lies around 25 or 27. For purposes of comparison it will be interesting to tabulate some of the coefficients in use. Very few municipal building codes adequately cover this type of construction, and some of these work on the cantilever principle, notably Portland, Oregon, so that it is not possible to make an extensive table.

Authority.	Moment coefficient.	Authority.	Moment coefficient.
Grashof	26.5	Turner	50
Mensch	20	Brayton	12
McMillan	25	Cleveland building code	27

The following table is given by G. C. Stone and will serve as a comparison of the results to be obtained by these methods. The original table was the work of A. B. McMillan and covers six methods, to these Brayton added the result as it would be according to his method, for the sake of comparison Stone added the figures for a slab, beam, and girder design, and the figures for Ham's method were added by the author. The comparison is defective because the same stresses are not used throughout. The steel stress in Turner's method is 13,000 lbs. per sq. in., in all others it is 16,000 lbs. per sq. in. This is probably justifiable because the low stress used by Turner may be said to be an integral portion of his system of figuring. In the figures according to the Cantilever and Turneaure and Maurer's methods the concrete stress is 750 lbs., and so far as the author has been able to determine 650 lbs per sq. in. is used in all the other designs. The only apparent reason for using the high stress is that by so doing the slab thickness is kept down to a value which compares with that obtained by the other

methods. Unless the cantilever principle of analysis has some feature that would justify the use of a higher stress than otherwise, we cannot consider the comparison absolutely fair for all concerned. It is, however, the best obtainable.

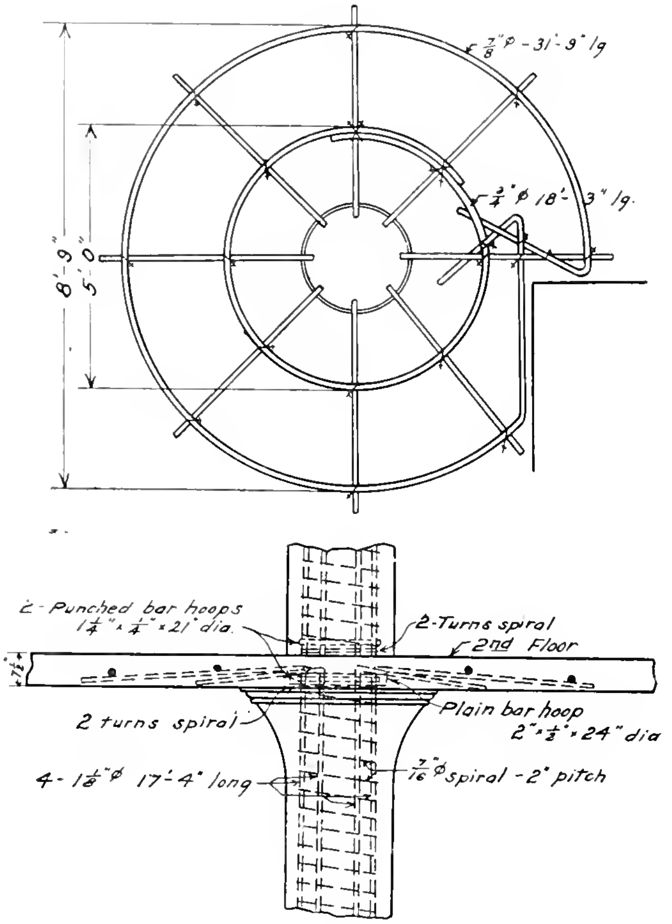

Fig. 5.

The following table gives the design of a panel of a floor according to the flat slab system as figured by various designers. The panel is assumed twenty feet square and is to carry a live load of 200 lbs. per sq. ft.

Authority	Slab thickness.	Steel in lbs.	Cost of steel
Cantilever	8"	2,189	\$87.56
Turneaure and Maurer	12"	1,931	77.24
Ham	8"	2,378	95.12
Brayton	8½"	1,900	76.00
Turner	8"	718	28.72
Grashof	8"	784	31.36
Mensch	8"	2,120	84.80
McMillan	8"	1,084	43.36
Average	8.6"	1,638	\$65.52
Slab, beam and girder	12"	2,300	92.00

The design of the radial steel cap on the column head which supports the bands of reinforcing is mostly a matter of economy and ease of erection. There are several patents on these caps, and one must either pay a royalty to the inventor or use a design materially different and probably inferior. In some of the designs it is certainly permissible to figure on their carrying a certain amount of stress; in others the practice would be indefensible. In general, it may be said that their function is primarily to hold the reinforcement in position, and any stress which they may carry is a secondary consideration only. Fig. 5 shows the details of a typical cap of this kind, it being Turner's design. It would appear to be very efficient although the wisdom of utilizing the main column reinforcement in this way might be questioned.

The reinforcing steel in usually plain medium steel bars of ½ in. or ⅝ in. diameter, used as they come from the mill and cut to length. They are commonly allowed to sag into position by their own weight, but it is much better if they are bent to the proper shape. This may be economically done by means of a right and left double-bar bender, which bends the bar to the exact shape at a very low cost.

The concrete is usually a 1:2:4 mix for broken stone or an equivalent one for gravel, no stone larger than ¾ in. being used. It should be mixed wet enough to flow readily around the reinforcement, it being generally recommended that it be of about the consistency of brick mortar. Where joints or bulkheads are necessary they should be made in a vertical plane and at or near the centre of the slab.

On December 13th, 1911, a new building code came into force in Cleveland, Ohio, embodying the latest knowledge on the subject of reinforced concrete building construction. It is particularly complete, and the design of floors by the flat slab system is given careful attention. There are many matters of importance which have not been dealt with in this thesis because not much information on them is available. These include the conditions in end and corner panels, the effect of narrowing the panel, the design of wall beams, and wall and corner columns. These questions are covered by the Cleveland building regulations, and in conclusion little better can be done than to quote some of the clauses of the code which refer particularly to the flat slab system of floor construction.

"Unit Stresses.

Medium steel in tension	16,000 lbs. per sq. in.
Concrete in direct compression	500 lbs. per sq. in.
Concrete, extreme fibre in compression	700 lbs. per sq. in.
Concrete in diagonal tension	40 lbs. per sq. in.

The compressive stress in the steel shall not exceed $\frac{c\,Es}{Ec}$ where c is the compressive stress in the concrete.

"Flat slab construction shall be figured with a bending moment in any quadrant over the column head of not less than $\frac{Wl^2}{27}$ in foot lbs, in which w is the total load per sq. ft., dead and live load; and l is the length in feet of the side of an equivalent square in rectangular panels, and the side of the square in square panels. This length shall be taken centre to centre of columns. The bands of reinforcing shall be made approximately $\frac{7}{16}\,l$ in width. In solving for the required area of steel over the column head, the distance from the compressive face to the plane of steel assumed shall be from the centre of gravity of all the steel to the under side of the slab. Any additional steel required over the column head shall extend beyond the centre of the column a distance not less than 0.3 l in all directions.

"The radial bars may be assumed as resisting tension, provided they are carried a distance horizontally not less than 0.1 l before bending downward; and further, that the allowed area of each radial bar figured to resist tension shall constitute not over one-half of the area of any single band of continuous reinforcement. The diameter of interior spirally

reinforced columns shall never be less than $\frac{l}{13}$ for floors nor $\frac{l}{14}$ for roofs, and the diameter of column head shall never be less than $\frac{l}{5}$; and this head, if constructed of concrete, shall be dropped below the under edge of the slab at least three inches at the outer edge.

"Rectangular panels shall never be less in thickness than $\frac{l}{45}$ the diagonal distance from centre to centre of columns for floors, and not less than $\frac{l}{50}$ for roofs.

"The minimum thickness of slabs shall be $6\frac{1}{2}$ in. for floors and 6 in. for roofs.

"The required percentage of steel in a single layer of bars shall not exceed 0.44% for medium steel or 0.30% for high carbon steel. In any flat slab type of construction provision shall be made to take care of circumferential stresses.

"In end or wall panels in which columns of reinforced concrete with heads are omitted, allowance shall be made for the increased moments. These moments shall be assumed to be 10% greater than the moments in the interior panels.

"If wall columns are used they shall be calculated to carry one-half the panel load plus any other loads, and if necessary the columns shall be designed for eccentric loadings. The wall beams shall be designed to carry one-third of the panel load plus any other loads. The minimum width of wall beams of reinforced concrete shall be 12 in., and never less than one-half the depth of the beam."

ELECTRIC STEERING-GEAR.

In a new method of controlling electric motors used for operating ordnance, steering-gear, swing bridges, etc., a rotatable resistance box is geared to the driven apparatus, so that when the contact arm is moved, and the apparatus is set in motion, the box follows the arm until the latter stands at the "off" position, when the motor comes to rest. The rheostat is arranged to act on the fields of both the dynamo and the motor, so as to reverse the direction of the latter without affecting the direction of the former.

The Robb Engineering Company has been completely reorganized with increased capital under the name International Engineering Works, Limited. The engine and boiler plants at Amherst, N.S., will continue to build the full line of horizontal and vertical Corliss engines, single-valve, high-speed, and English type of vertical compound engines, etc., so well known throughout Canada.

Tar as a covering for iron work must be used with great care, inasmuch as the crude material contains sulphuric acid and ammonia. This may cause serious pitting and rusting. Furthermore, it does not adhere well to bare metal and should never be applied except as a covering for other pigments The refined product offers the advantage of great resistance to foul atmospheres and corrosive gases. On account of its dark color the presence of rust cannot be easily detected.

FLOORS AND FLOOR SURFACE FOR FACTORIES.

H. N. Allott, C.E., in the course of an address to the Manchester Society of Engineers, says that for shop floors laid on concrete, where the work is of a heavy description, the best floor surface is one of wood blocks, 4 inches deep, which may be formed by sawing off 3-inch deals to lengths.

To prevent damp from rising through the concrete, the upper surface of the foundation should receive a coat of coal-tar pitch about ¼-inch thick, applied hot, and the blocks should be dipped in the hot coal-tar and bedded while the pitch is hot, any open joints being afterwards run in with pitch.

Where the work is of a lighter character, the most satisfactory wearing surface is grooved and tongued maple planking, nailed either to 4 by 3-inch battens laid in the concrete, or to planks laid transversely.

The battens should be creosoted, or dipped in "jodelite" or "sideroleum," or some similar wood preservative, and the planking laid in hot tar. It is very important that the whole surface of the floor should be thoroughly tarred before the wood blocks or planking is laid, and that any wood blocks or pegs used for levelling purposes should be removed.

Where the loads are very light and the foundation good, tar concrete may be substituted for the cement concrete, the upper surface being tarred as before.

The supported floors of a multi-story building, or of galleries, are usually constructed of concrete where a fire-resisting floor is required, or of timber in other cases. Where a concrete floor is used it may be constructed of reniforced concrete, or preferably of rolled-steel joists and concrete, as the more or less concentrated loads from machines and materials coming on the floor can be more easily arranged for.

In this case the floor can be constructed of small steel joists from 4 to 7 inches deep, according to the span and load, spaced about 2 feet apart, and finished with a flat ceiling. If the concrete is arched or recessed between the joists, hangers can be easily attached by hook bolts to carry countershafting. Another method, where the loads are considerable, is to use joists of heavier section, and to form an arched floor of concrete between these.

The upper surface of the floor can be finished with wood planking as previously described. If the floor is constructed of timber, wood joists bedded on the steel main girders can be used, with wood planking laid on top.

AUSTRALIAN RAILWAY GAUGE.

A conference of the chief engineers of the Commonwealth and state railway departments in Melbourne has urged the immediate adoption of a uniform 4 ft. 8½ in. gauge throughout Australia. The estimated cost of carrying this into effect is $185,000,000.

According to Prof. J. Goodman, in his paper read before the Institute of Civil Engineers, the safe load for a roller bearing, when the speed is not abnormal, may be calculated by the formula $P = Klnd^2 (ND + 2{,}000d)$, in which P is the safe load in lb.; l and d the length and diameter of rollers, in in.; n the number of rollers in the cage; N the r.p.m. of shaft; D the diameter of shaft or sleeve upon which the rollers run; and K a constant which has a value of from 1,200,000 to 2,000,000 when steel rollers are used, the workmanship is of the highest class, and when all surfaces are hardened and ground. For bearings with cost-iron casings and soft steel rollers and shafts, where the workmanship is of an ordinary grade, K may be taken at about 400,000.

CANADA'S ESTIMATED EXPENDITURE, 1913-14.

The following carefully compiled table will be of interest to readers of the *Canadian Engineer*. It shows the estimated expenditure of the Dominion for the fiscal year to end March 31st, 1914, together with the grants which were made for the year ending March 31st last. The table also includes a statement showing the increase or decrease for each service when the two fiscal years are compared.

Service	1912-13	To be Voted, 1913-14	Authorized by Statute	Total	Compared with Estimates 1912-13	
					Increase	Decrease
	$ cts.	$ cts.	$ cts.	$ cts.	$ cts.	$ cts.

A new pulp mill is being constructed for the Abitibi Pulp and Paper Company in the vicinity of Lake Abitibi.

It is stated that the management of the Intercolonial Railway is to pass from that of a board of managers into the hands of a single commissioner, who is Mr. F. P. Gutelius, who was formerly superintendent of the Canadian Pacific Railway, and for the past year has been engaged in an investigation of the construction of the Transcontinental Railway.

In 1907 Canada imported 533 traction engines, valued at $588,234; in 1908, 698, valued at $6,043,723.

Manganese steel dredge buckets are to be used to overcome the difficulties experienced in excavating the Pacific entrance channel to the Panama Canal. The experiment is being tried, as the carbon steel buckets which are now in use are not sufficiently strong to endure the hard digging. The new buckets have a capacity of 35 cubic feet each and weigh 5,400 pounds.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

Present Terms of Subscription, payable in advance
Postpaid to any address in the Postal Union:

CONTENTS OF THIS ISSUE.

MONTREAL FILTRATION PLANT.

In Montreal some conflicting opinions among engineers are forming the basis of much controversy concerning the $5,000,000 filtration works under construction at Verdun, to supplant the city's present water supply system.

It will be remembered that, in 1910, Montreal called in the services of Messrs. Hering & Fuller, consulting engineers, of New York, to report on the prospect of a safer and better supply of water for the city. In July of that year the engineers submitted their report, recommending the use of St. Lawrence River water, subjected to double filtration. The recommendation was adopted, and they were retained to co-operate with Mr. Janin, chief engineer, and Mr. Lesage, engineering superintendent of waterworks, in the preparation of plans and specifications and in the supervision of building operations.

Of the four contracts into which the work of construction was divided, those covering the building of the prefilters, filtered water reservoir and final filters, were awarded to Mr. F. H. McGuigan, contractor, of Toronto. Details regarding the general type of construction were published in the January 18th, 1912, issue of *The Canadian Engineer*.

Owing to ill-health Mr. McGuigan found it necessary to discontinue operations last fall, and the work, which had progressed favorably through several months, was taken over by Mr. Norman M. McLeod, contractor, of Montreal.

Recently Mr. McLeod served the city council of Montreal with a protest, alleging that the site chosen by Messrs. Hering and Fuller, in conjunction with Mr. Janin and Mr. Lesage, was most unsuitable for such a structure, the soil being insufficiently firm, owing to the presence of quicksand. He also claimed that there were serious defects in the design of the filters, and that severe cracking and similar symptoms of failure and collapse were in evidence. He predicted that the structure would be of little usefulness when completed. Opinions of prominent engineers, familiar with the conditions, corroborated, in whole or part, Mr. McLeod's statements.

Acting upon a joint petition from the Board of Trade, the Fire Underwriters' Association and the Canadian Manufacturers' Association, a board of independent engineers was appointed by the city, to inquire into the situation, carefully inspect the site, and ascertain to what degree the contractor's statements were founded upon fact. Messrs. P. W. St. George, J. A. Jamieson and Frank A. Barbour formed the personnel of the board. At the same time the city officials were strongly of the opinion that insufficient protection from frost last winter had been the cause of the pronounced subsidence and cracking of the foundation and walls, the uncompleted filters having remained open and empty during the months of frost.

It is understood that the board of examining engineers has made a thorough study of the ground upon which the structure is being built, and that the earth has been found by them to be quite suitable for the purpose.

The probable result of the report is predicted to be that the contractor will be required to complete the filtration plant according to specifications, and that the responsibility of damage by frost may not be charged to other than himself.

Because filtration plant installation is, as yet, in a more or less experimental stage in America, from the difference of opinion among Montreal engineers concerning suitability of site, it is to be expected that information of value to other cities and towns with similar problems ahead of them, will be derived.

OCEAN FREIGHTS.

The question of advances in ocean freight rates, both import and export, is of considerable importance to engineering and contracting supply houses, and many will be interested to know that it has again been discussed by the Montreal board of trade. It was decided to call the attention of the government to the matter, with a view of learning whether Great Britain and the other maritime nations could be induced to take joint action for the control of rates. As a preliminary step the transportation bureau committee of the board recommended that the Dominion government should be asked to appoint a commission of inquiry with a view to arriving at all the facts in connection with the advances in rates that have taken place within the last few years.

The question of ocean rates arises periodically. It is alleged, and generally believed, that they are regulated by combination. The question was investigated to some extent by Mr. Richard Grigg, chief Canadian Trade Commissioner, when he held the position of British Trade Commissioner in Canada. In a report to the Imperial Government in 1907 he said: "It must be a matter of opinion as to whether rates of carriage are higher than the service warrants, and if they are, it is perhaps easier to state the fact than to formulate a remedy. Assuming them to be so, it would appear that part of the preference designed to encourage the import of British manufacture goes into the pockets of steamship owners, and thereby to some extent defeats the intention of the preference by checking the import of British goods. Of course, no such conditions operates in regard to American goods, which are not subject to ocean carriage.

"It seems only reasonable to suppose that the officers of a company or conference whose employment and advancement must be justified by results, will strive to use every means placed at their disposal for the advancement and profit of the service to which they are attached unless restrained by policy imposed upon them by higher authority, and if this be so, the question is considerably narrowed. The condition with regard to the deferred rebate by means of primage (which is incapable of concealment) appears to establish the desire of the conference to discourage competition, and so to maintain rates; and the remaining problem is the extent to which the line of policy indicated is pursued. The answer is important to British trade, and it appears desirable that it should be sought and the whole facts made known upon competent authority."

That was apparently an appeal to the Imperial Government to investigate the matter. The subject of the control of ocean freight rates has frequently been brought to their attention, but little progress has been made with a view to an unbiased investigation. Meantime shippers pass sheafs of resolutions and the shipping companies are looking after their own interests.

EDITORIAL COMMENT.

The Canadian Electrical Association meets in Toronto June 25th, 26th and 27th. An excellent programme has been prepared and special rates are at the disposal of those desiring to attend.

* * * *

In his report for the year 1913, just issued, the Commissioner of Works for the city of Toronto recommends the construction of 20,400 feet of cement concrete sidewalks, 2,050 feet of asphalt pavements, 400 feet of brick pavements, and 10,000 feet of concrete pavements. His recommendation also includes 4,000 feet of curbing.

* * * *

An interesting feature of Col. Ruttan's report to the Winnipeg City Council, concerning the city's water supply project, is his proposal to bring the supply into the city through a tunnel to be driven through the rock below the bed of the Red River, the tunnel to be of sufficient size to carry three or four forty-eight-inch pipes, with provision for future extensions.

* * * *

A Convention of the American Waterworks Association will be held in Minneapolis during the week of June 23rd, and a very complete programme has come to hand concerning the papers to be read, the reports to be presented and provision for entertainment. It is not unlikely that Canadian cities will be well represented. At any rate the nature of the proceedings will be of great value to Canadian waterworks engineers. The Society for the Promotion of Engineering Education hold their convention in Minneapolis at the same time, and at one session the two organizations will hold a joint meeting.

* * * *

The Government has awarded the contract for the construction of lock-gates on sections three and four of the Trent Valley Canal. The southern portion of the canal is thus nearing completion. It is also reported at Ottawa that tenders will shortly be called for the beginning of work on the northern section, from Lake Simcoe to Georgian Bay via the Severn River. This will complete the waterway from Georgian Bay to Lake Ontario. To date, the canal has cost in the neighborhood of $11,000,000, and will require approximately $5,000,000 before it is finished.

LETTERS TO THE EDITOR.

Sir,—Referring to the article under the heading "Disadvantages of Chemically Pure Water as a Beverage" in your issue of May 15, the writer came across an instance of its truth a few years ago in Gibraltar, where the naval authorities, for a while, supplied all the dockyard staff in government quarters with distilled water which had not been aërated.

The use of this water brought on constipation, and for a time caused a good deal of unnecessary discomfort to the unfortunates to whom it was supplied.

Distilled water was largely sold to the citizens by the sanitary commissioners during the dry summer months, but this was properly aërated and no trouble ever seemed to result from drinking it.

Yours faithfully,

ALFRED S. L. BARNES.

Toronto, May 22, 1913.

THE PLOTTING OF RAILWAY CURVES

A METHOD OF PLOTTING TO A DISTORTED SCALE—SUITABLE FOR RELINING EXISTING CURVES—DOUBLE TRACK WORK—STATION LOCATION ON CURVE, ETC.

By J. L. BUSFIELD, B.Sc., A.C.G.I.

In a paper read before the British Institute of Civil Engineers in 1909 by Mr. W. H. Shortt, A.M.I.C.E., on "Railway Transition Curves," a method of plotting railway curves was described, together with the mathematical proofs of the accuracy of this method, and also details of some of the uses of this method in practical railway work were given.

Mr. Shortt, in his paper described the interdependence of scales in distorted diagrams in the following way: "If a given circular arc be plotted with the radius struck to a scale of $a \times b$ feet per inch, and the length of the arc marked off to a scale of a ft. per in., then a scale of a/b ft. per in. must be used to scale off the true distance of any given point from the arc, **provided such distance is small compared with the radius of the arc.**"

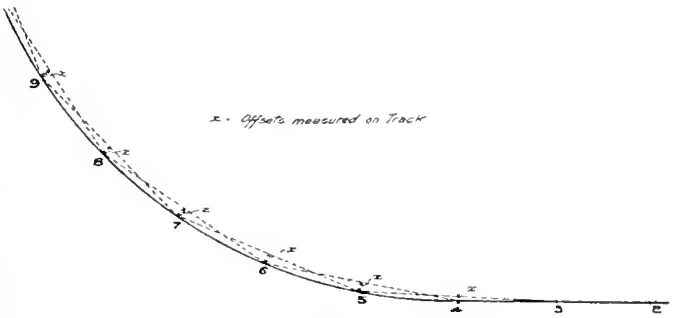

Fig. 1.

Now, for general use scales in the proportions of 100 to 10 to 1 should be used for the radius, arcs and offsets respectively, i.e., if the radius of the arc is made 400 ft. per in., and a distance measured along the arc to a scale of 40 ft. per in., then the small measurements at right angles to the arc can be made to a scale of 4 ft. per in.

This method of plotting has been used with success in Great Britain, and the writer has used it for different purposes and found it satisfactory for practical use.

The use to which it was originally put in Great Britain was for the re-alignment of existing railway curves, with the insertion of transition curves where they did not formerly exist. A preliminary survey was first made of the curve to be remodelled, by marking off on one predetermined rail, consecutive stations, one chain length apart, commencing at a point on the tangent at least 2 or 3 chains before the commencement of the curve. After this was done the curvature was obtained by means of taking offsets from chords 2 chains long. This was very rapidly and easily performed by stretching a cord between alternative stations and taking the offset at the intervening station. In addition to this all controlling features, such as the edges of the fills, or cuts, bridges, tracks, platforms, etc., were located by means of offsets from the rail used as a base line.

The survey thus obtained of the track and adjacent structure was then plotted to a distorted scale, preferably using either the 100-ft., 10-ft. and 1-ft. per in., or the 200-ft, 20-ft. and 2-ft. per in. scales. This was done by laying off the tangent and then plotting the chords by the offsets obtained in the field, and then joining up the ends of the chords with a continuous curve, as shown in Fig. 1. The full line representing the alignment of the rail used as a base line, and the dotted lines showing the chords and offsets x by means of which the curve was located and plotted.

In Fig. 2 the same curve is shown by the dotted line, the construction lines being erased, and the controlling structures have been plotted, also to the distorted scale, and from these the maximum shift permissible on either side is obtained. In the figure the arrow heads represent the limits between which the rail may be moved. The next thing to be done is to fit on an improved alignment. This is shown as finally completed by the full line.

The best position for this improved alignment is obtained by trial. A curve is drawn to the same distorted scale of about the same radius, and a transition curve is inserted between the points marked A and B in Fig. 3. The curve DBC is drawn with a radius approximately that of the curve on the ground with the beginning of curve at point D. The correct distances DF and FA for the transition curve can be computed from various formulae, then B the end of the tran-

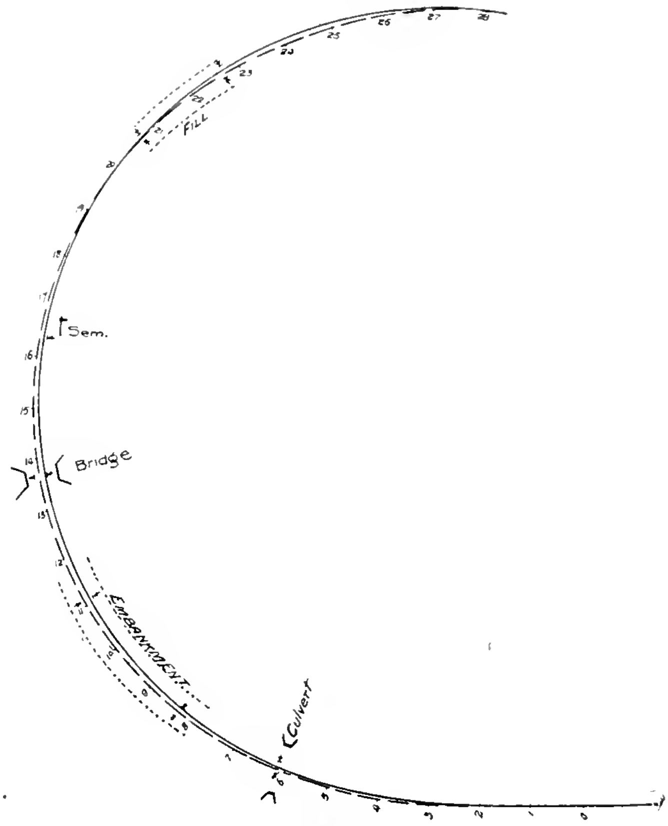

Fig. 2.

sition curve is located by making DB = FA, and also G, bisects DF, so three points on the transition curve are obtained. The intermediate curve can then be readily plotted

as a cubic parabola, by dividing AF and DB into an equal number of parts, and taking cubic proportions of the distance GF. If this curve is plotted on tracing paper, it can then be superimposed upon the original alignment curve and by trying different curves a suitable one can be obtained to give the best alignment with the minimum shift of track and keeping within the defined limits, as shown in Fig. 2. The distance the track has to be moved at each station can now be measured off on the diagram to the correct scale, and if these measurements are then staked out in the field and the track lined over a good alignment will be obtained. This is only one of the simpler cases in which this method of

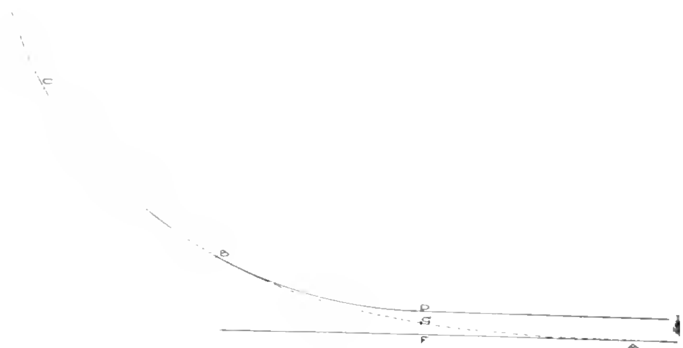

Fig. 3.

plotting was used, and other more complicated ones are described by Mr. Shortt in his paper.

The writer has used this method of plotting curves for two different purposes and found it very satisfactory in both cases. The first case was for relining existing railway curves, with the insertion of a spiral curve without disturbing the centre portion of the curve more than absolutely necessary to make it truly circular.

The first step was to draw to a scale of 100 ft., 10 ft. and 1 ft. to the inch, distorted diagrams of different curves varying by ½ degrees up to the maximum curvature likely to be met with. An example being shown in Fig. 4, where ADC represents, say, a 3-degree curve. It is now required to insert a spiral without altering the location of the tangent of the centre of the curve. To do this it is necessary to calculate the distance S required for a spiral to a curve slightly sharper than the original one plotted, and also to calculate the length of spiral required for this curve. The line EG should then be drawn parallel to the tangent AD, and a curve EFC drawn tangent to EG at E, and tangent to curve ADC at C, care being taken that EC is longer than half the length of spiral, and then a cubic parabola can be drawn in, as shown by the dotted line ABF.

Starting from the BC of the original curve 25 ft. or 50 ft. distant are marked off to the 10-ft. scale, along the arc DC and also along the tangent DA, and at each of these points the offsets x are measured between the circular curve and the spiral curve ABFC. As the scale for these offsets is 1 ft. to the inch they can be measured within a ¼ of an inch, which is just close enough for track work. The offsets can then be tabulated for the different degrees of curvature, ready for use in the field.

In staking out a curve with the new alignment, the BC is located in the usual way and the transit is sighted along the tangent and stakes put in every 25 or 50 ft. (according to choice) from the BC, each being offset a certain amount according to the tables, until the point of spiral is reached where the stake is set on the centre line. The transit is then reversed and angles deflected in the regular way round the curve, the stakes again being offset the correct amount until the end of the spiral is reached. In this way the curve ABFC is staked out on the ground.

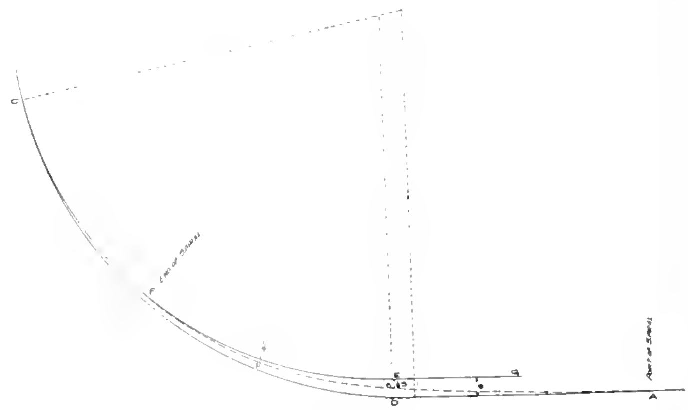

Fig. 4.

This method, though not theoretically correct, has the great advantage that it takes no more time in the field than it requires to stake a simple curve, and it also gives a satisfactory spiral without changing the central portion of the curve. The writer has used this method frequently on main line work and found it perfectly satisfactory. In one instance a 5½° curve at the foot of a 1% grade was spiralled in this manner, and the trains passing onto this curve did so in a smooth and easy manner. The portion of the curve CF that is sharpened above the main curve can be made so short and of such a small amount sharper that it is practically negligable.

It frequently happens in railway double track work that it is required to take advantage of a curve in the tracks to increase the distance between the centres of the tracks; for example, if a bridge is required at the centre of a long curve it might be desirable to use a girder between the two tracks which would have to be separated to perhaps 15 ft. centres instead of 13 ft. Another instance where this occurs is at stations located on a curve, it may be desirable to put a platform or standpipes between the two tracks requiring 18 ft. to 20 ft. centres at the centre and only the standard 13 ft. centres at the ends of the curve. The distorted curve diagram can readily and easily be used to assist in the laying out of work of this nature.

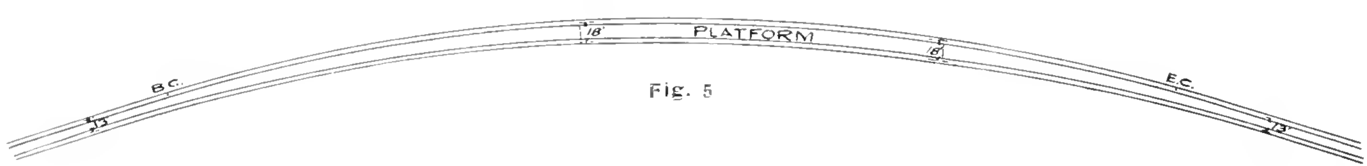

Fig. 5

Taking the case where a 13-ft. platform is necessary between the two main lines, as shown in Fig. 5, at the ends of the curve on the tangents the tracks are 13 ft. centres and opposite the platform the tracks are 18 ft. centres and parallel, so that between the ends of the platforms and the tangents the two tracks have to converge 5 feet.

In laying out this work one track would be staked out as a uniform curve in the usual way, and one method of locating the second track would be to run intersections at either end of the curve and then stake these out independently of the first curve. This method takes considerable time and requires several men to do it. The other method is to plot a 3-scale curve which will facilitate the work, requiring the time of one man for about half an hour to do the necessary plotting.

The method of procedure is to draw the tangent and regular curve as staked out on the ground, and shown in Fig. 6 by xyz. If a 100-ft. scale is used for the radius, the distance from the BC to the beginning of the platform GF is scaled off 10 ft. to the inch. Now we have the condition that the two curves must be parallel at the platform and 18 ft apart, and also parallel at the tangents 13 ft. apart, or the same result is obtained by assuming 2 curves to run from the one

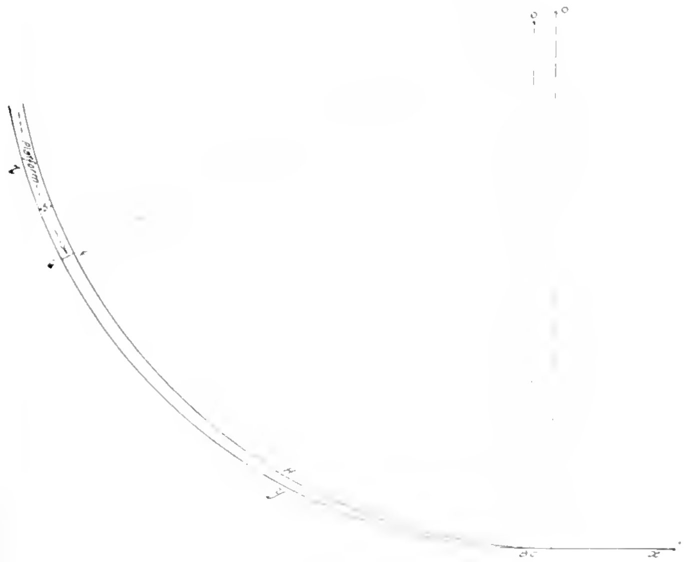

Fig. 6.

tangent and spread out 5 ft. apart at the platform, or at the point G in Fig. 6. Now, making FG = 5 ft. at 1 ft. = 1 in., it is now necessary to draw in a curve with its centre on the line GO, or GO produced which will also be tangential to the tangent X. This curve is shown FHX.

Equal distances can now be marked off along the tangent and curve XYZ, corresponding to the positions of the stakes on the ground. The offsets between these points and the new curve GHX can now be scaled off and made us into tabular form. If necessary, the process should be repeated for the other end of the curve and the tables giving the station of the stakes (or numbers for identification) and the corresponding track centres opposite each stake should be given to the track foreman who will then be able to give the second track its correct alignment.

This method has been used by the writer with success, and it has proved to save time in the field and work more satisfactorily than staking out individual curves.

The International Geological Congress will be tendered a reception by the civic authorities on Monday, August 12th. Delegates will be received in the council chamber, city hall, by His Worship the Mayor. It is understood that the Federal and Provincial Governments are providing for similar receptions to the delegates on their extended trip across Canada. It is expected that the convention will be attended by over eight hundred members.

LAYOUT, DESIGN, AND EQUIPMENT OF INDUSTRIAL PLANTS.

By A. Home-Morton.

The importance of an adequate amount of time being spent upon the design proper in the creation of industrial works and establishment of industries is receiving increasing attention as a special branch of Applied Engineering involving the consideration of every problem which might arise from the conception to the realization of the enterprise. In recent issues of *The Canadian Engineer* the design of a structural steel plant was carefully dealt with, every phase bearing upon construction and subsequent operation receiving its due amount of attention. In a paper read recently before the Liverpool Engineering Society Mr. A. Home-Morton dealt with the design of industrial works in general, dividing his subject into six sections, viz.: General and financial considerations; labor and labor conditions; general arrangements; generation and transmission of energy; design and consideration of the works structure; and reconstruction.

Efficiency and Economy.—The stress of competition in modern industry demanded efficiency with economy in every department. Industrial engineers were in consequence frequently called upon to supplement estimates of the capital cost of a projected undertaking with estimates of the working costs, maintenance, and even of profits. These demands in proprietors' interests were, under certain conditions, legitimate and desirable, and the engineer-designer must be able to satisfy the proprietor with such estimates, accurate to within a moderate percentage. Careless estimating ought to be inconsistent with professional honor.

Due consideration of and for the worker was now being accepted as a sound business policy. There was a tendency toward improved labor conditions and the reduction of physical drudgery by the introduction of aids to labor.

A certain school of economics contended that the increase of mechanical appliances tended to lower the standard of excellence and skill in handicraft, and, consequently, the intelligence of the craftsman, but it was equally true that the greater perfection of the results, increased rate of production, and usually greater reward obtained with mechanically aided labor tended to improve labor conditions, and to uplift, rather than to degrade, the worker.

It must be clear that in order to secure not only quantity but quality of output, the interest and skill of the worker and the perfection of equipment must be maintained unimpaired.

A general arrangement must be considered with reference to the character and quantity of the output, and the limitations and disabilities of the site. Actual plants designed to produce the same commodity on sites of varying form were found on examination to have similar essential areas, even although they might differ somewhat in arrangement. This suggested a relationship between floor area and output, which, theoretically, ought to hold, and on investigation would be found to apply even in plants which had grown from humble beginnings. Such a ratio of floor area to output would vary with the magnitude of the output, although it would probably hold for average conditions over a considerable range in magnitude.

Processes and Routing of Work.—The first essential to a general arrangement design was the "process diagram," and the second the "routine diagram." The process diagram was simply the enumeration in tabular form, or the graphical presentment, of the several shop processes. When to a graphical diagram of a process of manufacture was added a complete schedule of the areas required to house the machines necessary to produce a given output, then a complete "process diagram" was the result.

From the process diagram and the basis areas already mentioned, the engineer-designer with an intimate knowledge of the whole process of manufacture, and of the machines necessary to accomplish the process in each particular section, might proceed to prepare the routine diagram, which represented graphically the flow of work in process. In preparing this, the plant should be so arranged that the material dealt with and manufactured should flow through them in an orderly manner, in one direction, so far as might be, and without waste of time, energy, or material.

The routine diagram was probably the most difficult part of works design. It involved the sequential arrangement of the machines within each department, and thereafter the laying out of the departments relative to each other To carry this out successfully required great skill and care, and probably much tactful discussion with the proprietors, managers, and foremen of the proposed works.

From the data available, however, suitable approximate linear dimensions and heights for buildings might be fixed, and thereafter the manipulation of these blocks might proceed until the most satisfactory relative positions of departments were secured. The routine diagram was complete when the several departments were arranged on paper, and the flow of work in progress through the departments was as perfect as possible. The first design was rarely final, for the final plan was usually a combination of the leading features of several draft plans.

It could not be too well remembered that the buildings should accommodate the plant, that the process of manufacture should not require to accommodate itself to the buildings, and that the transmission of power was an integral part of the scheme, and must be considered from that standpoint.

The subject of power generation and transmission in industrial works had been frequently and exhaustively treated in recent years. The mass of information was, however, so technical, so varying, and so conflicting in its conclusions as to be, in a great measure, beyond the grasp of most power users. The first conclusion, and that to which it was difficult to reconcile the partisan mind, was that each system of power generation and transmission had its particular advantages and superior economy, and that maximum economy in works driving in a particular case might be obtained by a combination of two or more systems.

Transmission of Power.—The difficulty was usually not so much the selection of the system as the determination of the extent to which it should be utilized. Where the plant was compact and conveniently arranged within a radius of, say, 100 or 150 feet, from the central power plant, mechanical transmission was economical, while with an increased radius, gas or electrical transmission had advantages. In small works and factories the most careful thought ought to be given to the works design in order to ensure a compact arrangement and efficient mechanical transmission. The chief advantages of the electrical transmission system were its adaptability and the ease with which it could be extended.

Under the industrial conditions which held to-day and were becoming increasingly stringent, no manufacturer who was building or reconstructing works or mills could afford to neglect the technical skill which was at his disposal quite irrespective of cost. It might be argued that a works manager or proprietor knew most about his business and its needs.

But it could be urged quite legitimately that the proprietor's business might be the mining of coal, or the manufacture of iron or steel, ships, chemicals, or textiles. In that sphere he was at his best, but in the design of buildings, the selection of power plant, or even the economical arrangement and correlation of them he was at a disadvantage. Whether this disadvantage was serious or might only involve a permanent tax upon his business, when accepted, must be left to his own judgment.

Those industries which held a world-wide reputation in America, in Germany, and in England had in every instance been either originally designed or reconstructed by experts.

HIGH-TENSION CONTINUOUS-CURRENT TRACTION.

In a paper in which he considered the high-tension continuous-current system of traction M. L. Gratzmuller discussed the generation of such current, the overhead conductor, the motors and their accessory apparatus, the control, and the safety of the system and the protection of the staff. He also described a few recent installations.

In concluding, he remarked that the title high-tension continuous-current traction was not very happy, as it implied an entirely new type of apparatus, whereas in fact it only marked steady development. From 500 volts it passed to 600 volts, and then to 750 volts. The trains from Villefranche to Bourg-Madame used current at 850 volts. Certain sections of the Budapest system were now run at 1,000 volts, and to-day the system was applied to locomotives at 2,400 volts, and even 3,000 volts was talked of. This progress had been justified by improvement in the commutation of the motors, due principally to the use of auxiliary poles and to recent methods of insulation by means of mica and impregnation. The cost of transmitting the energy must not be overlooked in view of the weight of copper required for the lines and the cost of sub-stations. In order to make a comparison with other methods of traction—viz., single-phase and three-phase—the length of the line and the intensity of the traffic should be taken as independent variables. Heavy traffic was a favorable factor for high-tension continuous-current traction.

The advantages of continuous-current were principally the large starting torque, the quality of the commutation (which was shown by the small wear of the commutator and the brushes), and the light coaches. On the other hand, there were the drawbacks of the use of an exposed high-tension rotating part—particularly dangerous in damp localities—the use of a commutator, and the control of the large currents necessary when a large amount of power was required.

CANADA'S SHARE OF IMMIGRATION.

A total of 52,580 British emigrants, left the United Kingdom for countries outside of Europe during April, 1913. As many as 37,948 proceeded to other parts of the Empire, 29,984 going to Canada and 5,533 to Australia. Of the remaining 14,632, all but 603 went to the United States.

In the first four months of the year 133,350 natives of the British Isles emigrated, over three-fourths of whom have been retained within the Empire. They were distributed as follows:—

Canada	66,911
Australia	23,432
New Zealand	4,881
British South Africa	3,366
Other colonies and possessions	3,418
Total British Empire	102,008
United States	25,522
Other foreign countries	2,820
Grand total	133,350

PERMISSIBLE DILUTION OF SEWAGE.

By George W. Fuller, M. Am. Soc. C.E.

At a meeting of the hydraulic, sanitary and municipal sections of the Western Society of Engineers the more salient features of the sewage dilution problem formed the subject of a most instructive paper. Reference is made at the outset to the extensive literature concerning the Chicago drainage canal, the various streams of Massachusetts which the State Board of Health has subjected to report, and the general scheme of sewage disposal for the metropolitan district tributary to the New York harbor, as well as to the more recent investigations carried on by numerous large cities throughout America. The subject matter of the address directly pertaining to the permissible limits of sewage dilution is contained in the following:—

The liquid portion of all sewage or water-carried waste must go to the water courses sooner or later. The only exception occurs where the sewage is evaporated. Mention is made of this feature in order to accentuate the thought that the water courses of this country must receive the water-borne wastes in some form or another. The question becomes, therefore, one of the degree to which liquid wastes are improved as to their quality before they are finally disposed of by dilution in some water course.

It is perfectly obvious that as civilization advances, and the population of the country increases, there can be no longer any streams of original pristine purity. That condition absolutely disappears, and such disappearance is one of the penalties of civilization. On the other hand, there are a great many streams in this country—some large ones, as well as numerous small ones—which are over-polluted with water-borne wastes. This is due to an overstepping of the proper limits of permissible dilution which we are to discuss here.

Definitions.—Sewage is defined as the spent water supply of a community together with those trade wastes and street washings which in some instances are removed in underground channels called sewers.

Sewage Disposal.—The art of sewage disposal means the economical elimination or prevention of nuisances with respect to these water-borne wastes.

Types of Nuisances.—Nuisances due to sewage naturally are grouped into two classes: One refers to conditions that are offensive to the senses of sight and smell. The other refers to the hygienic aspect of the matter and to the transmission of disease germs contained in the sewage to neighboring communities through the water of the stream into which the sewage is discharged. These disease germs refer, of course, to those of the water-borne group, such as typhoid fever, Asiatic cholera, and others of intestinal origin.

The hygienic aspect of sewage disposal is naturally related in many instances to questions of water supply. It is also intimately associated with shellfish problems along the seaboard. Public health officials also have to deal with this aspect of the question with respect to public bath houses and possibilities of transmission of certain diseases by flies from deposits along the shore of some highly polluted water courses.

Hygienic Aspects of Sewage Disposal.—The sterilization of sewage discharged into tidal waters in the general vicinity of shellfish layings has within the last few years proved an economical and, in the hands of careful operators, an efficient means of dealing with one of the important phases of the hygienic side of this question. While there are only a few sewage sterilization plants now in operation, there have been a dozen or more recommended for adoption and it seems unnecessary here to state more on this question in view of the thorough discussion which it has received from Professor Phelps in Water Supply and Irrigation Paper No. 229 of the U.S. Geological Survey. Hypochlorite of lime, or some similar sterilizing agent, has a great future before it in the treatment of sewage at places where shellfish are found within certain distances.

Sewage disposal in its relation to public water supplies is, of course, the most important hygienic feature, and it is a question upon which viewpoints vary widely. Some believe that all sewage should be purified so thoroughly that it will practically resemble spring water and so that there will be no need of water purification.

In the opinion of the writer all questions of water supply and sewage disposal should be viewed in the light of all local conditions, having in view that the treatment adopted should give the best returns for the money spent when due regard is given to the benefit derived in the interests of the public health.

The Royal Commission on Sewage Disposal of Great Britain has considered this question at length and its conclusion was as follows:

"We are satisfied that rivers generally, those traversing agricultural as well as those draining manufacturing or urban areas, are necessarily exposed to other pollutions besides sewage, and it appears to us, therefore, that any authority taking water from such rivers for the purpose of water supply must be held to be aware of the risks to which the water is exposed, and that it should be regarded as part of the duty of that authority, systematically and thoroughly, to purify the water before distributing it to their customers."

"Apart from the question of drinking waters, we find no evidence to show that the mere presence of organisms of a noxious character in a river constitutes a danger to public health or destroys the amenities of the river. Generally speaking, therefore, we do not consider that in the present state of knowledge, we should be justified in recommending that it should be the duty of a local authority to treat its sewage so that it should be bacteriologically pure."

The conclusion of the commission is a sound one and as a general proposition water purification rather than sewage purification affords a better safeguard of the public health in the present state of the art. It is also to be noted that water purification is not only more reliable, but it is also cheaper under most conditions.

In this connection it is to be borne in mind that untreated surface water supplies as a rule do not afford a thoroughly safe drinking water. The reason of this is that there are too many opportunities for pollution from the soil wash and indirect sewerage of small villages and hamlets, and the infection of the water from the casual huntsman, fisherman, or those who for pleasure or business traverse the watershed. There are, of course, exceptions to this rule, but they are growing fewer and fewer. This is well shown in Europe where, since the great cholera epidemic of Hamburg some years ago, it is an unwritten but practically effective law that all surface water supplies shall be filtered.

Many large cities in this country are provided with combined sewers, the entire flow of which at times of storms can scarcely be purified completely. It is true that hypochlorite of lime has proved to be of much help in securing an improved quality of drinking water at many places, but the fact remains that as a general proposition the surface water supplies in this country should be filtered in order to make them thoroughly first-class in point of hygienic character.

While it is believed that the purification of public water supplies in this country is a subject that must stand on its own feet first and foremost, it is undoubtedly true that there

are some exceptions to this rule and that sewage purification sometimes should be provided to aid the neighboring water supply. The medical man feels that everything that can be done to destroy disease germs should be done, and is inclined to say purify all sewage and also purify all water. This brings up the question of much practical significance of how a certain expenditure of money can be best applied in the interests of the public health.

The water purification should come first so far as the hygienic side of the matter is concerned, and sewage purification or perhaps sewage treatment by sterilization should come into play in order to make sure that water filters are not overloaded if there is likelihood of inferior quality of filtered water being furnished the consumers.

Double filtration of water supplies and the judicious use of sterilizing arrangements and the advantageous employment of coagulating processes can all be brought to the aid of the water purification plant. Even with all of these precautions as to the water supply, there are times when purification of the sewage of a neighboring community or of the community whose water supply is under consideration, should be carefully provided for. We shall say no more on this question of the hygienic aspects of sewage disposal, as it is hoped that the viewpoint has been made plain that the dilution method of sewage disposal is not barred from this line under ordinary circumstances. The limitations in the dilution method are really to be found in relation to the nuisance question as noted by sense and smell, and this is the question that we shall now proceed to discuss at length.

Nuisances as Related to Sewage Dilution.—Sewage dilution is an important, rational, and proper method of disposal of sewage if it is properly applied and is not abused. Disregarding the question of disease germs which we have already considered, the dilution method of disposal is a proper one when by dispersion in water the impurities of the sewage are consumed by bacteria and larger forms of plant and animal life, or otherwise disposed of so that no nuisance results.

The dilution method is by far the most prevalent one now in use in this country. As our knowledge becomes more precise as to its advantages and disadvantages, the conclusion becomes more clear that the method has not been applied in a satisfactory way in a large number of instances. On the other hand, there seems to be no good reason why advantage should not be taken of this method within reasonable limits. Between the so-called complete purification of the sewage and the dilution method there are intermediate procedures which allow advantage in point of economy to be taken of the dilution methods, and at the same time the nuisances to sight and smell, which have been so common at various places, may be effectively prevented.

Nuisances attending the sewage dilution method may be due to, (1) floating solids; (2) settling solids; (3) non-settling putrescible organic matters.

These three constituents, or groups of constituents, in sewage explain most of the difficulties that are encountered to-day with the sewage dilution method. We can all recall instances where orange peel and other household wastes float in bodies of water around sewer outlets. We are also accustomed to deposits of "sewage mud" or sludge near the outlets, and the likelihood of their decomposing and producing foul odors particularly at times of low stream flow. There is also the condition where there is inadequate dilution of the sewage as it enters the stream, and where the entire body of water turns black owing to anaerobic decomposition or so called septic action.

Clean Rivers.—There is undoubtedly a well-defined movement on foot to free American rivers of small and moderate size of solid organic matter and filth coming from the flow of sewers. This movement, in my opinion, is a proper one and, when combined with adequate purification of water drawn from rivers receiving such sewage, the whole question of sewage disposal by dilution assumes a more reasonable and favorable aspect than hitherto. Furthermore, it does not involve communities in the expense called for by sewage filtration. It modifies, however, the limits that are permissible as to sewage dilution and calls for a recasting of the engineer's views and calculations upon the question. We shall outline briefly some of the features involved in the permissible limits of sewage dilution in connection with "clean rivers."

Screens.—In America there has not been as much progress as in Europe in the use of screens or other arrangements by which floating matters objectionable to the sight are removed from sewage as it enters the stream. In Germany so-called fine screens with an opening of 0.4 in. or less have had many warm advocates. The fine screens have not the standing to-day that they had a few years ago, in the opinion of many engineers, owing to the success attending the sedimentation devices as a cheaper and simpler means of keeping back floating matters and at the same time of removing the coarse heavy solids that subside. In America fine screens have been regarded with questionable favor, owing to the cost of their maintenance. We shall not discuss the relative merits of different devices, but will confine ourselves to the statement that without question floating matters should be removed from sewage before the latter is disposed of by dilution in an adequate body of water.

Sedimentation Tanks.—An examination of the Massachusetts State Board of Health reports, and other American data on pollution of streams, quickly shows that the stranding of solids in the vicinity of sewer outlets has in the past proved one of the drawbacks to the satisfactory use of the dilution method. This is particularly true at times of low river stages when banks of "sewage mud" or sewage sludge are exposed to "putrefaction" with attendant bad odors. Some 60% of the total suspended solids in the ordinary sewage are responsive to subsidence, and unless the sewage is discharged into a river with uniformly high velocities, these solids are bound to strand or settle. The removal of these "settling solids" is an important feature in the establishment of "clean rivers" in this country and, if we eliminate a few of the larger streams, it is my opinion that sedimentation of sewage is going to come into general use as a preliminary step in the modern arrangements for sewage dilution.

In earlier days difficulties in disposing of the sewage sludge or solid matters deposited in tanks were the cause of the slow adoption of this important improvement. It is true that chemical precipitation and sludge presses provided a solution of the problem, but at an expense that proved discouraging to many communities, and such that in Europe the cities near the seacoast were led to "barging" the sludge to sea. It is believed that septicization, particularly as embodied in tanks of the two-story type, will allow this matter in the future to be handled far more satisfactorily than in the past.

Unimportance of Organic Matter in Settled Sewage.—If a sewage has been clarified to such an extent that there will be no deposits in the stream bed at or near the sewer outlet, and if the disease germs are killed, there then remains to be considered the sanitary significance of organic matter coming from the settled sewage, and diluted with large volumes

of river water. In most cases where the sewage is diluted so that there is formed no offensive odors due to decomposition, and where the sewage has undergone sterilization, it does not seem likely to us that it is necessary in the interests of the public health to go to the expense in most cases of removing the dead organic matter of the settled sewage.

It is intimated by some that the germ theory of disease and the specific infection of water through disease germs does not necessarily tell the whole story as to the hygienic disadvantages of sewage-polluted waterways. On the other hand, the extensive investigations of the United States National Board of Health, as stated in their report for 1882, page 201, indicate that with sewage-polluted waters, it would be necessary to drink half a gallon at once of the waters under test in order to get as much nitrogen and carbon as is contained in a single medicinal dose of strychnine, which is stated to be one of the most energetic of recognized poisons.

A similar view as to the harmlessness of organic matter *per se* was stated by the late Dr. T. M. Drown in the Special Report of the Massachusetts State Board of Health, 1890, Part I., page 537.

A similar view has also been given by Dr. A. C. Houston, now chief water examiner of the Metropolitan Water Board of London, in the Second Report of the Royal Commission on Sewage Disposal, page 27.

"Organic matter *per se* in water is seemingly harmless; it is the bacteria likely to be associated with the organic matter that constitute the element of danger. Only bacterioscopic analysis can hope to reveal the kinds of bacteria in an effluent which are of a sort liable to be related to disease. Chemistry is quite powerless in this respect, and, indeed, all chemical standards of potability are apparently based on an assumed relationship, which may or may not exist, between the amount of organic matter and the number and kinds of the associated bacteria. Typhoid fever stools, whether sterilized and innocuous, or unsterilized and highly dangerous, would yield to chemical testing practically the same results as regards the nature and amount of organic matter present."

Furthermore, where there is adequate dilution of settled and sterilized sewage in a river used for a water supply, it is not difficult, as already stated, to effect a substantial removal of organic matters in works well adapted for water purification and involving coagulation, aeration, and sterilization by powerful oxidizing agents.

Degree of Dilution.—On the assumption that floating and settling solid matters are removed from the sewage and that disease germs are killed, where necessary, by sterilizing chemicals, we can now come to the discussion of what the permissible limits are for the dilution of sewage. We can answer it by saying first that the limits should be such that there should be present at all times and in all places sufficient dissolved oxygen to prevent anaerobic or so-called putrefactive decomposition becoming established, and furthermore that there should be a reasonable margin of dissolved oxygen to take care of fish life unless it should prove in some instances that the question of fish life is not of sufficient significance to justify consideration.

On the degree of dilution the first scientific data in this country were obtained in the early days of the consideration of the Chicago drainage canal, and it is from the technical staff of the Chicago Sanitary District that engineers have received their latest information bearing upon this important subject. A few years ago, and in fact until quite recently, all data as to the degree of dilution of sewage referred to crude sewage with its floating and settling solids. The Chicago drainage canal was established on the legal limit of 3⅓ cu. ft. of water per second to dilute the sewage of each 1,000 persons connected with the sewers. That limit was probably too low for the crude sewage of a city which has such a large proportion of manufacturing wastes in its sewage flow as is the case in Chicago. For a city without manufacturing wastes it is probably a fair limit, although some data obtained from Massachusetts suggest that it might be wiser to provide a somewhat more liberal volume of water for dilution.

Generally speaking, a dilution of 4 cu. ft. per second per 1,000 population is as close a general figure for crude sewage as can now be obtained, although undoubtedly there are various local factors which influence the dilution and may establish a range as wide as from 3 to 7 cu. ft.

As to the degree of dilution necessary for settled sewage, present evidence indicates that at least 2.5 cu. ft. per second per 1,000 population should be provided for residential communities and where the diluting water is well supplied with atmospheric oxygen. For manufacturing cities, where the diluting water is moderately depleted in oxygen during the summer months, this dilution may perhaps have to be doubled, that is, increased to 5 cu. ft. per second per 1,000 population.

There is no precise rule now available, and the above ranges establish as closely as can now be done the permissible limits in the dilution which properly should be applied to settled sewage in preference to raw sewage with floating and settling solids in it.

Dispersion,—Mixing.—One of the great drawbacks to the dilution method of sewage disposal as applied in earlier years was then the tendency to conduct the sewage only to the margin of the stream and perhaps only to the high-water shore line. This explains the nuisances that prevail in many American cities where the stream flow throughout the entire cross-section of the river is sufficient to provide reasonable results by the dilution method. Enough has been said to indicate that if dilution is to be advantageously used, it should be done under conditions where the sewage is so mixed with the stream flow that the degree of dilution above mentioned will be secured at all points. Naturally, streams with comparatively high velocities allow better results to be obtained than those in which the velocity is reduced or checked entirely at times by mill ponds or other obstructions.

Residual Oxygen.—This is a question upon which there are many divergent views. Until it is put on a more satisfactory basis than at present, it is hardly feasible to state the degree of permissible dilution more closely than given above. Colonel Black and Professor Phelps have advocated that a residual margin of 70% of dissolved oxygen should be provided for the waters of New York Bay. A more common opinion places this margin at 50%. Messrs. Wisner and Pearse (of the Sanitary District of Chicago) have put this margin at 2.5 c.c. of dissolved axygen per litre, which is equal to about 20% of saturation of oxygen during winter months, and 30% for the summer temperatures. These gentlemen, however, have reference to fish life. My own experience is that if stranded solids have been kept out of the stream there will be no occasion for difficulty as to anaerobic or putrefactive decomposition, provided there is some dissolved oxygen present in the stream at all times and at all places. One of the earliest and most important points established at the Lawrence Experiment Station was that a little oxygen, say, 1% to 3% of that necessary for saturation, would allow oxidation and nitrification to take place as satisfactorily or nearly so, as if the water were saturated with oxygen. I know of no reason for departing from the teachings of those early experiments at Lawrence, and I believe

that estimates of 50 or 70% for the required residual of dissolved oxygen can be explained only by extraordinary allowances made for the consumption of oxygen by existing sewage sludge, or by more than liberal allowances of oxygen for major fish life In fact, whatever margin is needed above a slight positive quantity at all times and places in the stream is, in my opinon, solely accountable for by the oxygen necessary for fish.

Fish Requirements.—Data are somewhat meagre as to the amount of dissolved atmospheric oxygen which is required in the streams to protect major fish life. The quantity no doubt varies with different species of fish and perhaps other local conditions. In the Lower Elbe near Hamburg it is stated that the margin of dissolved oxygen during the ordinary summer periods falls as low as 20%, and the figure in the Lower Thames is understood to be about 30%. At Hamburg there has been no serious complication as to fish life other than during the summer of 1911, when it is understood that for three or four weeks fish actually migrated from the vicinity of the city. This does not mean that there was any nuisance as to putrefactive odors. In fact, it is stated that none existed. It shows also another point and that is that since the fish returned after a period of three or four weeks, it will be quite debatable whether once or twice in a generation it is necessary to prevent the migration of fish, if by such prevention there will be involved expenditures of vast sums of money for the more complete purification of the sewage.

I was told in Berlin a year ago that an amount of residual dissolved oxygen equal to 1 c.c. per litre was considered sufficient under ordinary circumstances in the immediate vicinity of a sewer outlet, although 1.5 c.c. were preferable.

Fungus Growth.—Professor Thumm, of Berlin, has stated to me that in waters containing a great abundance of oxygen it is possible that offensive odors might result through the growth of certain fungi, namely, Leptomitus, Sphaerotilus and Cladothrix. The staff of the Royal Prussian Testing Station have observed that these growths are said to be characteristic of streams receiving a lot of industrial wastes, such as come from wood pulp mills. The growths seem to be favored by the presence of much putrescible organic matter, ample dissolved oxygen, and a high velocity of stream flow. These comments are not in harmony with my recollections of the life history of these organisms, unless it be that their growth is fostered in certain deposits which are dislodged under certain conditions. The question is an interesting one, and it is the only suggestion that I have heard of which limits the permissible dilution of sewage in other than by the dissolved oxygen, in cases where disease germs are destroyed or may be properly ignored. This is a question which needs further study, and it may be entitled to more consideration than we now realize in America.

Comprehensive Designs.—While a firm believer in the dilution method of sewage disposal within permissible limits, as roughly outlined above, I am aware that many American towns and cities are likely to grow to proportions where the dilution method will require more and more complete treatment of the sewage in order to be satisfactory. It is the part of wisdom to prepare designs for sewage disposal works so that if filtration is not needed at the outset it can be adopted as conveniently as practicable in later years and without embodying too great a sacrifice in works now undertaken. This means, among other things, that intercepting sewers, sites for screening plants, and sedimentation tanks could well be arranged with the idea that some day filtration also must be provided. If this were done it would probably save considerable money that otherwise might be lost.

Relaxations.—In England the principal topic of conversation among engineers was found to be the forthcoming report of the Royal Commission on Sewage Disposal and the disposition in that report to provide for "relaxations." By this is meant that there would be installed, piecemeal, works which would provide ultimately for purification to the degree set out by standards recommended by the commission a few years ago. It is proposed now to take full reasonable advantage of dilution, but to arrange the works so that further and more complete treatment may be secured when and as required in the future.

Separate Sewers.—So far as household wastes are concerned, in all new systems and in many cases of extensions to existing sewer systems, it will be helpful to adopt the "separate system" to a greater extent than has been the vogue hitherto. The prevention of a mixture of the sanitary wastes of the household with the storm water from the streets will aid materially in minimizing the expense and in increasing the success attending sewage purification, sewage treatment, and the utilization of the dilution method within safe practicable lines.

Finally, then, it is permissible to dispose of sewage by dilution provided that complications can be prevented so far as disease germs are concerned, and this should be best done in connection with water filtration, and further provided that offensive conditions to sight and smell do not result.

In some large streams, as in the lower Mississippi near New Orleans, sewage which is passed through coarse screens may with care be disposed of in a satisfactory way. In large lakes, tidal estuaries, moderate and small streams, it is important, if not necessary, for the success of maintaining "clean rivers" or "clean bodies of water" to free the sewage from floating and settling solids.

Permissible dilution of sewage without treatment in water courses with fairly high velocities ranges apparently from about 3.5 to 7 cu. ft. per second per 1,000 population, depending upon the manufacturing wastes in the sewage and the dissolved oxygen content of the diluting water. For well settled sewage, these limits become about 2.5 to 5 cu. ft. per second per 1,000 population according to present information.

INTERNATIONAL ENGINEERING CONGRESS, 1915.

In connection with the Panama-Pacific International Exposition, which will be held in San Francisco in 1915, there will be an International Engineering Congress in which engineers throughout the world will be invited to participate. This congress will be conducted under the auspices of the following engineering societies: American Society of Civil Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers, American Institute of Electrical Engineers, and the Society of Naval Architects and Marine Engineers.

A scale-testing car is being built by the United States Bureau of Standards for testing scales in yards, grain elevators, and other places where interstate traffic is handled. It will not itself be used as a load, but will carry movable weights, which will be used for testing. It is proposed to have the car carry a number of standard weights of 10,000 pounds each, and a large number of 50-pound weights. A truck, capable of carrying 50 tons, will be carried on the car to be used for moving the standard weights, in testing scales. The car will be equipped with a crane for lifting the truck and the heavy weights.

CALGARY'S PUBLIC UTILITIES.

Preparatory to striking the rate, based on the estimated expenditure for 1913, Calgary's city commissioners prepared a report on all the public utilities under their control. It showed:—

"During 1912 there were 47 miles of water mains laid, 324 hydrants set, and 3,116 new connections made to the mains. The expenditure on the aforesaid works charged to capital account was the sum of $558,846.52. The estimated revenue was $258,550.10, and the actual income amounted to $244,423.37.

"All bills chargeable to the waterworks system, up to December 31st, 1912, have been settled.

"The asphalt paving plant has been operated by the city since the month of July, 1912. Paving was constructed at an average cost of $2.10 per square yard; price quoted includes an allowance for debenture interests, sinking fund and plant depreciation.

"The capacity of this plant in 1912 was, approximately, 1,000 square yards per day, and the new unit now nearing completion will much more than double the capacity of the plant.

"The revenue derived from this utility was $87,558.02; the expenditure $103,247.38, $24,954.71 of the latter amount representing stock on hand, leaving a surplus of $9,265.53.

"The street railway has expanded beyond expectations. Starting operations in 1909 with two cars, half a mile of track and 16 employees, in December, 1912, the system had increased to 54 cars in operation, 60 miles of track, 246 regular men employed.

"During the past year it carried 14,627,370 passengers, earning a gross revenue of $603,975.38, with a total expenditure of $502,254.81.

"Its capitalization account stands at $1,615,000, of which has been expended $1,537,490, leaving a balance of $77,509.08 which is available for construction purposes.

"The electric light and power plant department, in the seventh year of municipal operation, continues to show gratifying financial results and satisfactory service.

"The normal peak load, namely, 7,000 horse-power, 5,000 horse-power of which is purchased from the Calgary Power Company, generating this energy by means of water-power obtained at Kananaskis Falls; the remaining 2,000 horse-power is produced by means of a battery of 16 boilers, six of which use as fuel, natural gas, and 10 coal, representing a total of 5,000 horse-power. There are 11 generators, whose prime movers consist of steam and electrical energy. The remainder of the city's power plant, representing 3,500 horse-power, is under stand-by to take over full capacity at short notice.

"The gross revenue received from the sale of electric light and power was $489,264.72, and the expenditure was $471,473.81, showing a net surplus of $17,790.91. The gross capital account amounts to $1,507,000, of which $1,454,017.40 has been expended, leaving a balance of $52,982.60. This makes a total gross plant account of $1,454,017.40."

The mill rate has not yet been officially announced, but it is expected that even though it has to provide for the unpaid bills of last year on sundry accounts, it will not exceed 16 mills.

Forest trees around the waterworks reservoir of Hornell, N.Y., will be planted by the Board of Public Works of that city in co-operation with the College of Forestry, of Syracuse University. It is stated that about 30,000 trees will be planted.

IRON AND STEEL PRODUCTION.

From the statistics which have just been published by the American Iron and Steel Institute relating to the production in the United States and in Canada of pig-iron and of iron and steel structural shapes, wire rods, and cut and wire nails, the increase in demand for these commodities in 1912, as compared with that of preceding years, can be fairly estimated. Taking the total of all grades of pig-iron, the increase of output by the United States between 1912 and 1911 was rather more than six million tons; and it is noteworthy that in making the 29,726,937 gross tons which constituted the output for 1912 the fuel consumed included 35,721,127 tons of coke, about 47,022 tons of bituminous coal, 73,794 tons of anthracite coal, and 35,436,017 bushels of charcoal, with over 15,000,000 tons of limestone and dolomite. In Canada there was also a substantial increase in output of pig-iron, thus maintaining the improvement which has been recorded year by year since 1903, with the single exception of 1908. The consumption of iron and steel structural shapes in the United States, which declined from the year 1909 to 1912, showed an increase in 1912. A feature of the figures representing output from the United States of these shapes, which include beams, tees, angles, and channels, and iron and steel for use in the manufacture of bedsteads, agricultural implements, fences, safes, plates, and girders, is that about 10 per cent. is exported, and that of these exports Canada in 1912 absorbed 169,952 tons, as compared with 103,054 tons in 1911. In 1912, the United States reached the maximum production of wire rods, and it is to be observed that in regard to the total 64,078 tons exported, Canada was again the best customer, taking 63,063 tons, as compared with 22,583 tons in the previous year.

REGINA IS WATCHING POWER EXPERIMENTS.

Regina's civic officials are desirous of solving the cheap power problem, and are following closely the experiments being made by Professor Darling for the provincial government. The board of trade recently had Professor Darling deliver an address when he very ably outlined his views. As the lignite coal fields from which it is proposed to develop power are about 150 miles from Regina, he proposes that the coal be carbonized, then shipped to Regina, and used as fuel for the generating of power. To generate the power at the mines and transmit it to the city would be an expensive proposition, he claims, unless numerous towns along the line, required power which is not the case at the present time. The cost of transmission such a distance would be very considerable. Mr. Darling has erected an experimental station at the coal fields, and the Regina board of trade intends to keep closely in touch with the results obtained, as the city is ever anxious to secure lower power rates for manufacturers, etc.

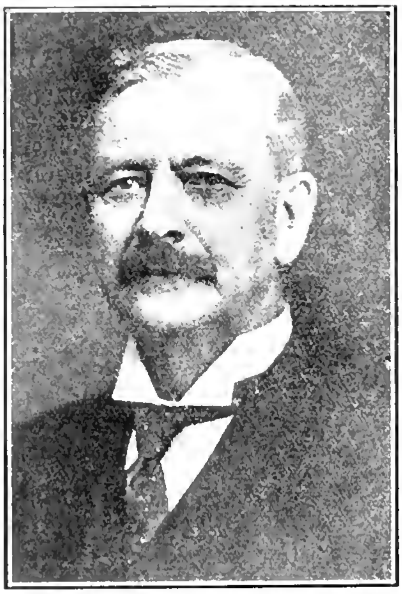
Mr. A. S. Porter, a well-known Regina citizen, who owns considerable coal lands, is organizing a $1,000,000 company for the purpose of developing power from the coal deposits on his land. He has set aside 15,500 acres of land to be mined for this purpose. A line of the Canadian Pacific Railway runs right through the property owned by Mr. Porter, and this he considers would make it an easy matter of getting the by-products such as briquettes, etc., to the cities and towns where they could be marketed.

Concrete work in the Panama Canal locks is nearly completed, the aggregate amount in place at the close of work on May 31, being 4,459,356 cubic yards.

ENGLISH INDUSTRIAL PLANT FOR MONTREAL.

The big industrial corporations of Great Britain and the United States are realizing the significance of the rapidly-growing markets of Canada. The United States Steel Corporation is establishing a large branch plant in Ontario and the Sir W. G. Armstrong Whitworth Co., Ltd., of England, will take a similar step, although their establishment will be in Quebec province. The company have acquired a site on the south shore of the St. Lawrence River, within Montreal harbor, and a plant will be erected there at an estimated cost of $1,000,000. This will be extended as often as needs justify. The Canadian branch of this famous company will be used solely for commercial or civil or mechanical engineering, and not for naval or military work. At no time will the company make guns, boats, or anything of that nature here. This is, at any rate, in keeping with the spirit of the celebration of one hundred years of peace in North America.

They will manufacture twist drills, punches, milling cutters, cranes, drop forgings, tool steel, etc.



M. J. BUTLER,

Largely through Mr. Butler's efforts and those of Sir Percy Girouard, the Armstrong Whitworth Company, of England, will establish a million dollar plant at Montreal.

The decision of this large English corporation to erect a branch plant in Canada is a great event in Canada's industrial history. It indicates the confidence of keen and observant business men and capitalists in Canada's future and that confidence is welcome and gratifying to Canadians.

British capital will finance the entire enterprise and no issue will be made in Canada. The share and debenture capital of the company is as follows:

	Authorized.	Issued.
Ordinary Shares of £1 each	£4,012,500	£4,012,500
Four per cent. cumulative preference shares of £5 each	1,000,000	1,000,000
Five per cent. non-cumulative second preference shares of £1 each	2,000,000	—
Four per cent. mortgage debenture stock	2,500,000	2,500,000

Largely through the efforts of Mr. M. J. Butler, of Montreal, was the company induced to locate a plant in the Dominion. He was successful in interesting their board of directors, however, only through the kindly co-operation of Sir Percy Girouard, a Canadian, and a director of the Sir W. G. Armstrong Whitworth and Company, Limited. To these two gentlemen, therefore, is chiefly due the establishment in Canada of such an important industry. Mr. Butler is well known as the former general manager of the Dominion Steel Corporation. Prior to that, he was chairman of the board of management of the Canadian Government railways, and previously deputy minister and chief engineer of the department of railways and canals. He is a member of several engineering societies, and has been engaged in some notable engineering projects in various parts of the Dominion. A contemporary recently described him as a man possessing "keen business instincts, systematic methods of work and all the firmness of the disciplinarian,"

Sir Percy Girouard was born in Montreal and gained his railway experience while on the engineering staff of the Canadian Pacific Railway. He acted as director of the Soudan Railways from 1896 to 1898. He was also president of the Egyptian Railway Board and later director of the railways of South Africa. As a military man he has served with honor in many engagements. Lord Kitchener described him as an officer of brilliant ability, and Lord Desborough has stated that he is a great civil servant who has succeeded in every position he has undertaken.

Oiling grade crossings so as to prevent a dust nuisance is being regularly practiced on the Delaware, Lackawanna & Western R.R. Two equipments are in use in different parts of the line, each consisting of an oil car provided with compressed-air tanks and special nozzles for spraying the oil. These cars are drawn along the line, and the crossings are oiled in succession by a crew that goes with the car, so that each crossing is oiled about twice each year. It has been found that this procedure is successful in keeping down the dust to such an extent that there is no offense from that source to passengers, particularly to those on rear-end observation cars, where before the oiling the nuisance had been great.

Mr. Frank Shuman, a distinguished American engineer, has installed near Cairo, a hundred horse-power sun plant for irrigation, and he has left London for Egypt to complete the installation and to begin operations almost immediately.

Four times only in the history of the human race has the generation of power been the subject of invention. First came the windmill, then the water-wheel. The third departure, and the greatest so far, was the combustion of fuel. Now comes the use of the solar rays, which, if successful, will be the most complete revolution of all, solving at once for the tropics the problem of fuel, which in the past has been so great a handicap to remunerative labor, and which in the future, with the diminishing supplies of coal, must become a greater handicap still.

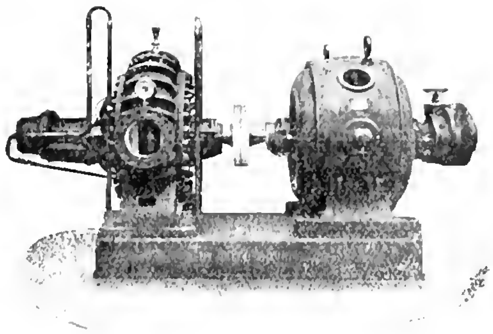
Explaining the character and purpose of his sun-power plant, Mr. Shuman said that "by means of parabolic mirrors the heat of the sun is concentrated to five times its natural intensity.

"This gives us a temperature of about 600 deg. Fahr., and by means of this heat concentrated on boilers the steam is generated, which is used for driving a low-pressure condensing engine. This engine in turn drives a large reciprocating pump capable of pumping 13,000 gallons a minute, and thus irrigating in this particular locality 1,000 acres of land

AN EFFICIENT HYDRAULIC PUMP.

The accompanying photograph shows a view of the "Victoria" hydraulicking pump. It is one of these pumps which was supplied to the Nipissing Mining Company. The pump, as shown, delivers 4,000 gallons per minute against a head of 415 feet, and has a speed of 1,180 revolutions per minute.

Details of the test made of this pump under actual working conditions will be found on the table accompanying this article, from which it will be seen that the efficiency in normal working reached 84 per cent. Boving & Company, Limited, who are the designers and manufacturers of this pump, and who are represented in Canada by Canadian Boving Company, inform us that similar pumps of various sizes have been sent to different parts of the world. It is interesting to note that the "Victoria" pump has the impeller automatically balanced, which obviates the necessity of a high-pressure stuffing box. One of these pumps installed at the Goss Moor tin mines has effected a great saving over the pumping methods previously used. The results obtained at Goss Moor are shown herewith and speak for themselves. The Victoria pump has been designed especially to overcome the difficulties experienced where water containing a large amount of mud and grit would cause heavy wear and tear. That it has done this effectively may best be seen from the results obtained in actual practice.



Some test results as obtained in the Goss Moor pump after it had been running for some time are given herewith. The engine is of the compound type, 11 in. x 19 in. cylinder diameter, 2 ft. 6 in. stroke, built by Messrs. Marshall.

Official Test Figures of Victoria Pump Supplied to the Nipissing Company.

The pressure readings were taken with test gauge on the top of the horizontal discharge of the pump. The pressure was very unsteady, the pointer vibrating about 5 lbs. The average is entered in the above table.

The vacuum readings were taken on the top of the horizontal suction pipe. The vacuum fluctuated about ½ inch to 1 inch during all tests.

The water was measured in a circular tank of 14 feet inside diameter, and the discharge from the end of the pipe was diverted into the tank by means of a "bucket" mounted on a truck. The truck was running on rails and the flow could thus be diverted very quickly. The results obtained on the amount of water discharged are very accurate, as there was no leakage or waste of water whatever. The time of diverting the water into the tank was measured by a stop watch.

The volt and ammeter readings were taken by the switchboard instruments, the kilowatt was taken by means of a standard instrument mounted on the switchboard. The total consumption during two hours continuous running was 1,000 kw. hours, corresponding to an average consumption of 500 kw.

At the National Physical Laboratory in England, there is a recently constructed road machine, which is the first of its kind in any country. It is a building containing a circular track on which experimental lengths of road can be readily laid down and tested to destruction by the passage over them of wheels driven by motors which are guided in the circular track by a revolving framework.

The machine is now at work. The track has been filled with four lengths of water-bound macadam made up in four different ways and the behavior of these lengths will be compared and each of them tested until it is broken up. The designers hope that by means of this machine they will be able to arrive rapidly at conclusions which otherwise would take years to reach on the actual roads themselves. The roadway is under cover and protected from weather influences, thus eliminating weather conditions entirely. It will be possible to introduce certain weather conditions one at a time and to study their individual effect.

For instance, the track can be heated by hot air blown upon it; rain can be imitated by spraying devices; it can be artificially cooled to the freezing point. The wheels used can be either standard wheels with plain steel tires carrying a fixed weight of one ton each; the diameter and widths of these wheels can be varied; solid rubber tires or pneumatic tires, plain corrugated or studded, can be substituted in turn and the effects of each on a road surface noted.

COAST TO COAST.

Toronto, Ont.—There is a tendency in some counties to distribute the county road work each year in short sections, rather than to take up one road and build it from end to end, according to Mr. W. A. McLean, Chief Engineer of Highways for Ontario, in his recent report. Work is scattered in this way for various reasons. Each councillor is ambitious to have some work done in the township he represents; there may be a fear that certain ratepayers will become dissatisfied if all the work is done in another locality; that the total expenditure may become exhausted before all roads are reached; there may be a desire to let all sections in the county see the class of work done on the roads, and to receive some early benefit; a wish to construct a section of road that is especially bad, or is largely travelled. The tendency is greatest in counties where there are numerous market centres or shipping points, and less in the counties with one well-defined centre, such as York with roads radiating from Toronto, Wentworth with Hamilton as a leading market, or Prince Edward with much traffic leading to Picton. To build roads in short sections in some cases may serve a useful purpose, but the practice is an expensive one and adds largely to the cost. Road-building is almost entirely a work of labor, and it is essential to economy that a well-arranged organization be created. It commonly takes a month to build a mile of road, and takes nearly that time to get the work going smoothly. To move the plant and equipment from place to place for every mile of road means that the work will be kept in constant disorganization, that laborers and teamsters who have become accustomed to the location will leave, and new men will take their place, that much time will be lost in moving the machinery from place to place while wages are still going on. Every move made means a loss of efficiency, loss of time, useless expenditure for wages, fewer miles built and a much increased cost. Short sections are justifiable and necessary in some cases, but to carry work on in that way as a fixed practice involves a useless increase of cost. The necessarily increased cost of "model roads" is not an expenditure which counties should assume.

Port Moody, B.C.—Preparations for the early construction of a sewer system will shortly be made. At a recent meeting of the city council the aldermen decided that a topographical survey of Port Moody would be advisable before undertaking the planning of a sewer system or its construction. This topographical survey will be made to ascertain the levels and the best location of main and lateral sewers, as well as outfalls and other details of their construction. From information gathered from this survey the council will be in a position to decide on the advisability of constructing a separate system of storm sewers or combining the two systems into one general scheme of drainage. Other statistics will be gathered by the engineers, who will do this work, and when the council is ready to lay out the system, the engineers will be prepared to give an accurate estimate of the cost of the entire system. The construction of a sewer system will, of course, follow the installation of the waterworks and the extension of this system.

Montreal, Que.—A model of the city filtration plant is under construction at Verdun on land of the same nature as that on which the ill-starred plant has its site. The model will be a replica of the plant in every important detail. Its pillars have been designed to carry a pressure of 2¾ tons a square foot—which is approximately the pressure exerted by the pillars of the plant. When the model is completed, the action of the soil will be carefully observed and minute tests taken of its power of resistance to pressure. The tests on the nature of the soil are the result of the protest which Norman McLeod, contractor for the construction work of the plant, recently filed with the city. Mr McLeod claimed the soil had an insufficient resisting power, causing the pillars to sink and a consequent upheaval of the concrete beds. The engineers for the city, on the other hand, contended the damage was due to the work not being properly protected from the effects of frost.

Victoria, B.C.—To construct the north-west sewer system of sufficient capacity to take care of a drainage area of 775 acres in Saanich, and approximately 1,000 acres in Esquimalt and make the proposed city system adequate for the future requirements, not only of that portion of the city alone, but also for the greater area covering the north-west section of the three municipalities, will cost in the neighborhood of $325,000, according to figures submitted by City Engineer Rust to the city council. The construction of the city system, including the main trunk outlet through Victoria West and on out to Macaulay Point will cost $240,000. To make this outlet sufficient for Saanich requirements in that section would mean an addition to the cost of $42,000, and to provide Esquimalt also with outlet facilities will mean a further expenditure of $43,000. The Saanich area addition would mean facilities for a population of about 11,000 and the Esquimalt addition for about 20,000. On the recommendation of the engineer, the two other municipalities will be approached with a view of coming to a mutually satisfactory agreement relative to the joint expenditure to provide larger accommodation, and also to an annual rental for use of the sewer. Esquimalt will be asked to grant permission to the city to drain ninety acres of surface water into the former municipality's surface drains which it proposes to construct. If this is done it will obviate the necessity of the city constructing a surface drain in the proposed sewer tunnel. City Engineer Rust stated that the engineers of Esquimalt and Saanich have practically agreed upon the plans of the proposed sewer system, but that the arrangements as to cost must be taken up by the respective municipal councils. Pending the submission of the scheme to the ratepayers of Esquimalt and Saanich, a tentative agreement could be arrived at. If the outside municipalities do not fall in with the proposed scheme, it would cost them in the neighborhood of $200,000 to provide an adequate sewer system for themselves.

Toronto, Ont.—Parks Commissioner Chambers hopes to make a start this summer on the construction of a complete system of boulevards, forty-two miles long, costing $7,000,000, and reaching around the city. The Parks and Exhibition Committee have appointed a sub-committee to make a trip over the proposed route, which is as follows: Lakefront, from Woodbine to the Humber, north up the Humber to Black Creek, east to Vaughan Road, north to York Mills, south through the Don Valley to the junction of the north and west branches of the Don River, east to Woodbine Avenue and south on Woodbine to the starting point at Woodbine Avenue and the lake front. The plan proposed would connect all the important parks in the city, in addition to many beauty spots in the county. The committee also decided to visit Hanlan's Point and look over the route of a 66-foot roadway it is proposed to construct along the west shore of Blockhouse Bay, from the Hanlan Memorial Park to a point near the Lakeside Home, a distance of 2,400 feet. The plan does not interfere with the waterfront development work contemplated by the Harbor Commission, and it is believed the road would relieve the congestion that always exists on the lake front on holidays and Saturdays. The cost of the work has not yet been estimated.

PERSONAL.

MR. F. S. B. HEWARD, Canadian manager for James Howden & Company, Limited, Glasgow, was in Toronto this week on a business trip.

M. W. SPARLING, B.A.Sc., has recently accepted a position at Campbellford, Ontario, as superintendent of the Seymour Power and Electric Company.

MR. ARTHUR C. HEAP, of the firm of Heap & Digby, inspecting and consulting engineers, of London, England, was a visitor to *The Canadian Engineer* offices this week.

Following the visit of Mr. G. B. Hunter to Canada, MR. WIGHAM RICHARDSON, of the celebrated Tyne shipbuilding firm, Swan, Hunter, Wigham Richardson, Limited, is now on a tour through the Dominion.

MR. WILLIAM STORRIE, acting waterworks engineer of Ottawa, has handed in his resignation, to take effect on July 1st, next. His two assistants, Messrs. H. M. Lee and T. C. Campbell have also resigned their positions.

R. G. SWAN, B.A.Sc., of Vancouver, B.C., has been appointed assistant chief engineer, Railway Belt Hydrographic Survey, of the Water Power Branch of the Department of the Interior, with headquarters at Kamloops, B.C.

W. A. McLEAN, provincial highway engineer for Ontario, and W. G. HENDERSON, president of the Manitoba Good Roads Association, were entertained at luncheon by the York Highway Board previous to their departure for Europe.

H. E. M. KENSIT, Mem. Inst. E.E., Mem. Am. Inst. E.E., electrical mechanical engineer of the Water Power Branch of the Department of the Interior, has accepted an appointment as Commissioner of the City of Prince Albert, Saskatchewan.

The appointment of J. T. JOHNSTON, B.A.Sc., as hydraulic engineer of the Water Power Branch of the Department of the Interior, with charge of water power surveys, investigations and inspection work in Manitoba, Saskatchewan and Alberta, has been gazetted.

MR. JAMES C. HARDING, consulting engineer, has opened an office at 170 Broadway, New York City. Mr. Harding has been engaged in the practice of hydraulic and sanitary engineering for the past 21 years, and has been a member of the firm of George W. Fuller for the last two years.

MR. JOHN S. MacLEAN has been appointed to take charge of the publicity and advertising work of the Canadian General Electric Company, Limited, and of the Canadian Allis-Chalmers, Limited, with headquarters in Toronto. The latter company, in addition to manufacturing an extensive line of machinery and appliances, will also act as sales agents for all the products of the Canada Foundry Company, Limited. Mr. MacLean held a similar position with Allis-Chalmers-Bullock, Limited, for a number of years.

MR. CHARLES B. BUERGER has joined the staff of Mr. George W. Fuller, 170 Broadway, New York City. Mr. Buerger entered the service of the Bureau of Filtration at Philadelphia in 1906 as a mechanical engineer, and was engaged upon the design, construction and testing of pumping stations and equipment. Later he was on the design of the preliminary filters at Torresdale and Belmont and had charge of the design of the Queen Lane filter plant. For the past two years he was senior assistant engineer in the Filtration Division of the Department of Water Supply in New York City on the design of Jerome Park filter plant.

ARTHUR H. BLANCHARD, M. Can. Soc. C.E., professor of Highway Engineering in Columbia University, sailed on June 12th to attend the Third International Road Congress, London. Professor Blanchard is a United States reporter on Question 3, "Construction of Macadamized Roads Bound With Tarry, Bituminous, or Asphaltic Materials," and Communication 10, "Terminology Adopted or to be Adopted in Each Country Relating to Road Construction and Maintenance." He has been appointed a delegate to the Congress by Columbia University, the American Society of Civil Engineers, the National Highways Association and the American Road Builders' Association.

MR. H. O. EDWARDS, who for the past twelve years has been advertising manager of the Canadian General Electric Company, Limited, and its subsidiary companies, has resigned. Mr. Edwards organized the advertising department of that company in 1903 and since that time has taken charge of all advertising, publishing of catalogues and technical bulletins as well as the purchasing of office supplies, stationery, etc. Mr. Edwards is to become sales manager of the Photo Engravers, Limited, 70 Bond Street, Toronto, where, no doubt, his long experience in the purchasing of engraving will serve him in good stead.

NOTICE OF EXHIBIT.

At the annual meeting of the Society for the Promotion of Engineering Education, which will be held in the Engineering Building of the University of Minnesota, Minneapolis, Minn., during the week beginning June 23rd. W. and L. E. Gurley, of Troy, N.Y., will have a representative exhibit of the instruments which they manufacture and which will include engineers' and surveyors' field instruments, water stage registers and current meters, physical and electrical laboratory apparatus, standard weights and measures, accurate mercurial thermometers.

Engineers and others interested will find that a visit to this exhibit will repay them, as an opportunity will be given to inspect the latest improvements in the instruments and to talk with the firm's representatives.

TENTH ANNUAL AMERICAN ROAD CONVENTION.

The American Road Builders' Association will hold its tenth annual Convention and fourth American Good Roads Congress in Philadelphia, December 9th to 12th, 1913.

The annual meeting of the Association is of great interest to those actively interested in road construction and maintenance. It always brings together the leading men identified with road building and street paving, for the purpose of discussing the problems in which they are vitally concerned. Plans are now being laid to make the Philadelphia meeting the largest and most important gathering of the kind ever held. As usual, there will be in connection with this meeting an exhibition, or rather exposition, of road and paving machinery, materials, etc.

The American Road Builders' Association was formed in 1902, and is the foremost organization of its kind in the world. Among its members are the leading road and paving experts, highway officials, engineers and contractors in America. The president of the association is Mr. Samuel Hill, of Seattle, Washington, who is also life president of the Washington State Good Roads Association, and is also identified with other good roads organizations. The other general officers of the association are as follows: First vice-

president, Mr. Harold Parker, ex-chairman Massachusetts Highway Commission; second vice-president, Mr. W. A. McLean, Provincial Engineer of Highways of Ontario, Canada; third vice-president, Mr. George W. Tillson, Consulting Engineer Borough of Brooklyn; secretary, Mr. E. L. Powers, editor "Good Roads;" treasurer, Mr. W. W. Crosby, Consulting Engineer.

AMERICAN SOCIETY FOR TESTING MATERIALS.

The sixth annual meeting of the American Society for Testing Materials will be held at Atlantic City, N.J., June 24th to 28th. A provisional programme has been arranged, according to which the following subjects will be discussed: "Preservative Coatings," "Steel," "Wrought Iron," "Cement, Concrete and Waterproofing," "Ceramics and Road Materials," "Non-Ferrous Metals," "Testing Apparatus and Methods."

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—The Twelfth Annual Meeting to be held in Canada during July and August. Opening day of the Toronto Session, Thursday, August 7th. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

THE INTERNATIONAL ENGINEERING CONGRESS.—Convention will be held in San Francisco in connection with the International Exposition, 1915.

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held at Chicago, Ill., Feb. 16-20, 1914. Secretary, E. E. Kraus, Harrison Bld., Philadelphia, Pa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—176 Mansfield Avenue, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, A. B. Lambe, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Muckleston; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 534 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Edmund Burke; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Bedford McNeill; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. J. B. Porter, H. E. T. Haultain and W. N. Miller and Messrs. H. W. Claudet S. S. Fowler, R. W. Leonard and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

TECHNOLOGY CLUB OF LOWER CANADA.—President, F. E. Came; Secretary-Treasurer, E. B. Evans. Meets twice yearly.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

An Engineering Weekly

PLATE GIRDER BRIDGES IN RAILWAY CONSTRUCTION

PART I

PREVALENCE DUE TO ADVANTAGES OVER OTHER DESIGNS —TYPES OF PLATE GIRDER SPANS IN USE—DIMENSIONING AND STRESS CALCULATION—VARIETY OF LOADS

By C. H. MARRS, C.E.
Erecting Engineer, Hamilton Bridge Works Company, Hamilton, Ont.

THE builders of iron and steel bridges for more than sixty years have maintained that steel bridges properly designed, with good material, efficiently maintained, and used according to the intention of their designers, have in every case proved entirely satisfactory and capable of indefinite endurance and that any cases of disaster have been due to some defect in the construction, to derailment, or other accidental occurrences which bring upon certain members unforeseen strains which they were not intended to carry.

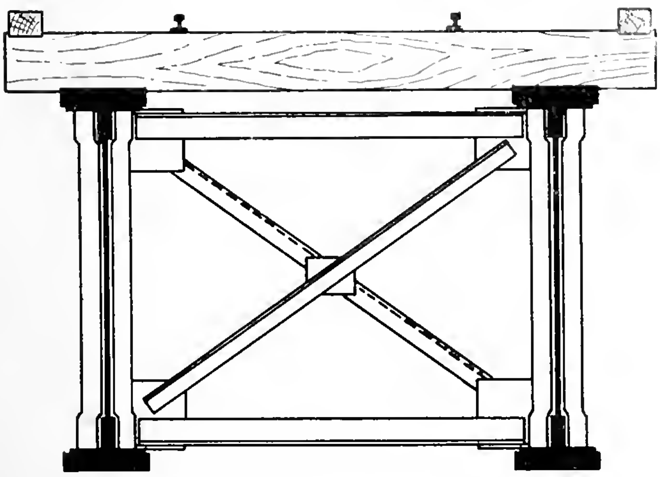

Fig. 1.—Type of Deck Plate Girder.

Of all types of steel railway bridges the plate girder span is the most common, as 75% of the extensive mileage of bridges built, is in the form of plate girder spans, and it is this great commercial demand which has suggested to the writer the importance of this subject.

Canada is still in her infancy in railroad construction, and in the future it will be necessary for a great many of our young engineers to have charge of the design and fabrication of plate girder bridges. Shop methods and erection facilities have so changed that text books do not give the young engineers all the information they require. It is not the object of this series of articles to explain the fundamental theories of plate girders, but to treat the subject from the standpoint of an engineer in actual practice, and to give an intelligible explanation of various snags which are not covered in text books, and which are either omitted in different specifications, or upon which they do not agree.

The advantages of plate girder construction over other forms of bridges are so evident that it is used wherever conditions will permit. One of these advantages is its solidity, by reason of which it is better fitted to resist injury from derailed trains, to prevent corrosion from sulphur gases, and to withstand the severe conditions of exposure which pertain to railway bridges. Another reason for the superiority of this form of bridge is its simplicity and uniformity of construction, there being a minimum likelihood for error in design. Moreover, the drawing-office expense and shop costs are reduced, as it is usually possible to standardize spans. The erection is completed in a shorter time than in the case of any other form of construction. There is usually more weight of material required in plate girder bridges than in lattice or truss spans, but this objection is more than counterbalanced by its cheaper pound price, the greater speed in the completion of the work and the longer durability in actual service.

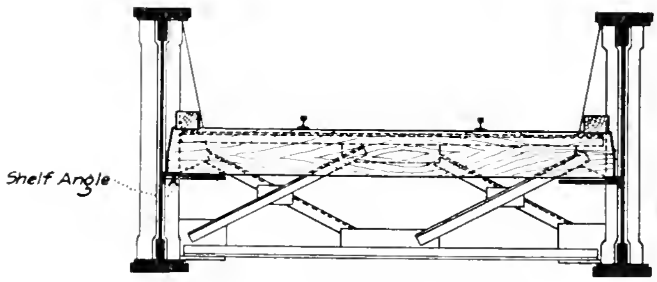

Fig. 2.—Half Deck Plate Girder.

The design of a bridge may be divided into two branches; first, the determination of the type of bridge most suitable and its dimensions, and second, the calculation of stresses and sections of material. After the site of the proposed bridge has been surveyed and the engineer has determined the grade alignment of the track, the allowable depth of clearance line below the base of rail and the most suitable lengths of spans required, the design of the bridge can be attained.

Types.—The various types of plate girder bridges which are in general use at present are represented in Figs. 1, 2 and 3, the deck girder being the cheapest and simplest form and therefore used wherever conditions of clearance will permit. Where the allowable depth for clearance is reduced to the limit where a deck span would not suit, it is necessary to adopt the half deck girder, as shown in Fig. 2, or the through plate girder type, as shown in Fig. 3. The half deck girder span is very little heavier than the deck span and is frequently used where the top flange is not more than three feet above the base of rail, the main girders being spaced 13 feet between centres. There have been bridges built where the shelf angles have been lower than this, and in some structures the ties have been made to rest directly on the bottom flange. This is not good practice, as it is necessary to space the girders further apart to suit the recognized requirements of clearance, and this would demand longer and

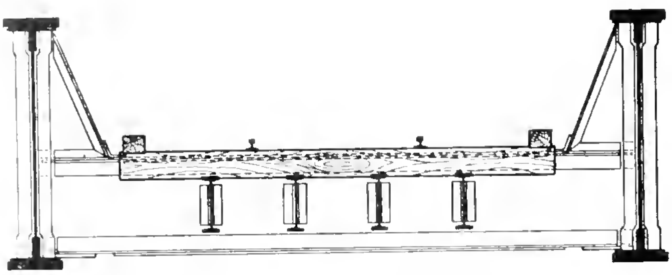

Fig. 3.—Through Plate Girder.

heavier ties and, moreover, the cross brace frames become so shallow that it is not possible to properly stay the top flanges of the main girders. The greatest objection to the half deck girder is that the ties resting on shelf angles must produce eccentric loading on the main girders, and this is not easily taken care of. The half deck span also requires extra heavy ties with an odd length, and these ties demand the most rigid inspection on account of the severe strain they undergo, and when it is necessary to replace them the procedure is much more difficult than in the case of the other types of girders because the ends of the ties butt into the webs of the girders.

The through plate girder span with stringers and floor beams, is undoubtedly the most desirable construction, where the depth of clearance is limited. Fig. 3 is an example of this form of bridge and shows four lines of stringers per track, which arrangement is considered to be better suited to support derailed trains, and which requires only a very light tie. But it is a cheaper construction, and quite as satisfactory, to use two lines of stringers per track.

In the case of railway bridges passing over streets in cities, where very shallow construction is an advantage, and where protection is needed for the street traffic, a solid floor is used. This may be accomplished by I-beams with a continuous cover plate, or by trough floor construction covered with a waterproofed concrete slab and ballast. The best type of trough floor is shown in Fig. 4. It is an expensive bridge and is not in very common use in Canada, but as railroads multiply in the larger cities it will be more necessary. The trough floor can be made shallower than any other type of floor for heavy loads, and is free from the noise of passing trains, which is an objection in more open construction.

Another type of solid floor, which is illustrated in Fig. 5, is being used in Canada by several railroads, even on bridges where protection below is not needed. It consists of regular track ties in ballast supported on concrete, which covers and fills in between the cross I-beams over the main girders. This construction is being used because of the scarcity of good large bridge ties, and the expense which is frequently required to replace these ties. Any construction which decreases the demand for timber is to be recommended, and there is a probability that bridge design may be considerably changed to suit the increasing scarcity of bridge ties.

There are some tube bridges still in existence, but they are not recommended in modern construction; nor is any form of box girder desirable where the inner surface is not accessible for painting. Wherever a box girder is used, it should be properly braced with diaphragms, so that it will not change its rectangular shape.

Dimensions.—In single spans the effective length of girders is dependent on the adopted clear opening between the abutments, as the edge of the masonry bearing plate should be six inches back from the face of masonry under coping. The length of the bearing plate can then be decided by an approximate calculation of the maximum end reaction. If the final calculations should give a slightly different required area of bearing plate, the difference can usually be taken care of in its width. The effective length of girders is the distance between the centres of these end bearing plates.

In bridges consisting of a number of spans resting on masonry piers, spaced at the most economical distance, the clear space between the ends of main girders should not be less than four inches, and the effective length of the girders is dependent upon this. In steel trestles where the girders rest on towers, the ends of adjoining girders should be placed as close together as the possible expansion will permit, and the effective length will depend on the adopted detail of seat, resting on the cap of the tower posts. In this construction, where the adjoining spans are of different lengths, the different end reactions will produce eccentric loads in the posts, which should not be neglected in the design.

The effective depth of main girders, which is the distance between the centres of gravity of flanges, is usually made to vary from ⅛ of length of span, for short spans, to 1/12 of length for long spans. If, for reasons of clearance, it is necessary to make the depth less than 1/12 of span, additional metal should be inserted so that the deflection will not be more than it would be with the above-mentioned depths. In bridges designed for very light traffic, it is more economical to use shallower girders.

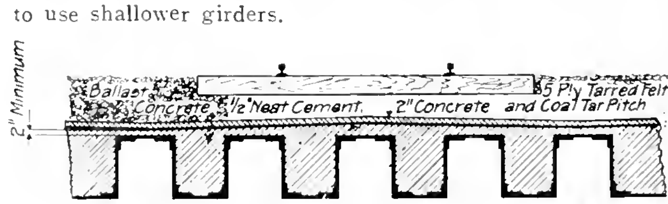

Fig. 4.—Cross Section Through Trough Floor.

There is a diversity of opinion among railroad engineers regarding the best spacing centre to centre of deck girders. This spacing consequently varies from 6½ feet for short spans to 10 feet for longer ones. Where the track is on a curve this spacing should be increased to accommodate the deviation of the track and to give additional stiffness to resist the centrifugal force of the trains.

Through girders are spaced as close together as the government clearance requirements will permit, and when the track is on a curve, this spacing is increased in proportion to the degree of curvature. A simple method of determining this required clearance is indicated in Fig. 6 and its accompanying explanatory note.

Skew in bridges should be avoided wherever possible, but it is sometimes necessary. It is less objectionable in girder spans than in trusses. Even though skew in the face of abutments is necessary, the ends of the girders should be

made square to the track, as this is a better arrangement for the deck. The character of the skew is termed right-handed when it is in the direction shown in Fig. 7.

The depth of the deck is the distance from the base of rail to the top of the girder, and when the track is on a tangent this depth is ½-inch less than the depth of tie required to support the wheel loads. Fig. 8 illustrates the C.P.R. standard track for deck girder bridges, and it shows the methods of securing the deck to the girders, and the amount of material required. When the track is on a curve, the base of the low rail is referred to in giving the elevations. The outer rail is given a super-elevation to suit the degree of curvature. This is usually made to suit a medium speed of train, rather than a maximum, as the rails are considered to wear longer with this arrangement.

This super-elevation may be arranged by tilting the whole bridge until the webs of main girders are normal to the plane of the track. By this method the standard deck can be used, similar to the case where the alignment of the track is tangent. This arrangement gives a minimum side thrust at the top flanges where the ties rest on the girders, and also a minimum strain on the bracing, because the direction of the axis of the bridge is midway between the vertical direction of the load, when the train is moving slowly, and the direction of the resultant force of the train at high speed. The more general practice, however, is to place the girders in a vertical position and provide for the super-elevation of the track in the framing of the ties. With this arrangement the bridge has a better appearance as well. The cheapest arrangement of the deck is to use regular ties with wood shims on the outer girder to provide super-elevation, but this is dangerous practice and should not be used. The best construction is the use of bevelled ties which can be detailed in the drawing room and ordered to suit. In this arrangement the depth required for the deck depends on the minimum depth of ties, over the inside girder, that is considered necessary to properly resist the shear stresses in the ties. This depth should never be less than 6½ inches, the worst position with the track on a curve being at the centre of the

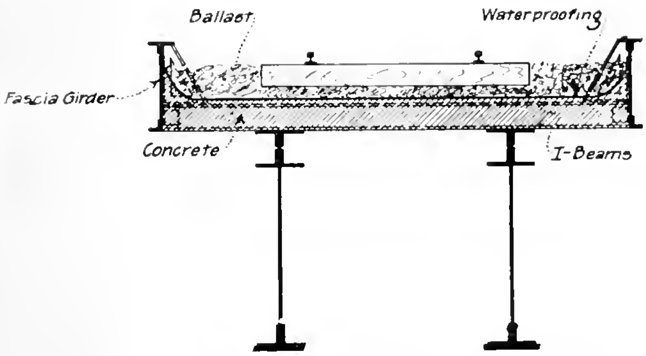

Fig. 5.—Cross Section Through Solid Floor I-Beam Construction.

span, where the camber is the greatest, the cover plates the thickest, and the lower rail farthest from the inside girder. So that if the depth of deck is decided at this point, the ties will have a greater depth towards the end of the span.

It is a common occurrence for engineers who do not correctly foresee the depths required for bridges, in the deck, in the girders themselves, and in the pedestals, to make mistakes in the construction of the masonry; and to overcome such errors it is often necessary to belly the bottom flanges of girders at the ends. This costs the contractor at least $200 a span for the steel, and is usually a total loss to him.

Camber.—This allowance is usually insisted upon for plate girder spans. The intention is to put sufficient camber in the span to more than overcome any possible deflection from loading, because a girder constructed straight might have a reverse camber when erected, which would have an unsightly appearance. A great many bridge engineers consider that this is unnecessary refinement, but if it is specified, good results can only be obtained by proper details and rigid shop inspection. Cases are known where two girders on the same span have reverse camber, although built from the same drawings and in the same shop. Another difficulty in regard to camber is in double track bridges when one track

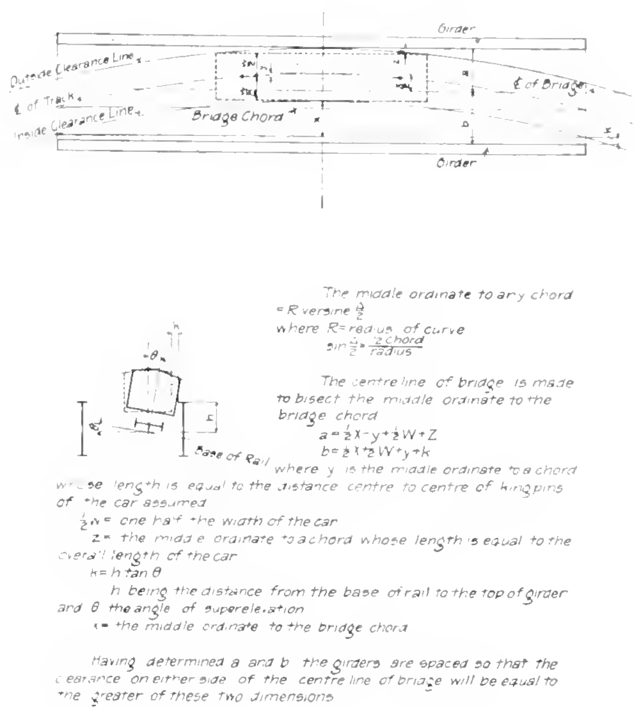

Fig. 6.—Clearance in Through Bridges on Curves.

only is loaded. Where there is one centre girder there is more deflection in the outer and lighter girder and where there are only two main girders there is more load carried by the one girder than the other, and therefore unequal deflection exists. The only arrangement to avoid this difficulty is to place two girders under each track, as if they were separate spans. This is a more expensive arrangement, but it is the best design, because the wear and tear on the bridge is lessened and each half is free to move and deflect by itself when loaded, without straining the other half which would probably be unloaded. It is often an advantage, too, in erection, as one track can be completed first, without interrupting traffic on the other track.

Calculation of Stresses.—In plate girder spans, as in all types of railway bridges, this calculation is based on the following loads: 1, dead load; 2, live load; 3, impact; 4, wind stresses; 5, centrifugal force when track is on a curve, and 6, traction. The methods, both analytical and graphical, for obtaining the dead and live load stresses, are fully covered in all text books on this subject and universally recognized in practice. As these basic methods are unaffected by evolution in construction it seems unnecessary to consider them here.

The dead load per lineal foot of track must be assumed to begin the calculations. It consists of the weight of material in the deck and the steel in the structure. In determining the deck it is usual to consider first the maximum axle load plus impact, distributed over three ties. This will determine the size of ties needed, and as the rails and guards and fastenings are standard, the weight of the deck is then

known. The weight of the steel must be assumed either by approximate methods or from records of weights of other spans, and when the design is completed a check should be made to make sure that these assumptions agree with final results.

The live loads adopted by various railroads are usually standard types of consolidated engines followed by a uniform train load and an alternate heavy concentrated load, and the different classes of loading are provided for by varying the loads in the same proportion throughout the whole train. In this way the calculations of stresses are simplified and the results are quite satisfactory, as it is impossible to foresee in every case the exact wheel loads which may be carried by the bridge. Moreover, by the adoption of this standard loading, tables of shears and moments for deck spans of various lengths can be made, which save time and labor in actual practice. In through bridges it is always necessary to calculate each bridge by applying the actual wheel loads.

Impact stresses should always be added to provide for the momentum of the live load caused by deflection of the bridge, the unevenness of the track, vibrations, and various other conditions, but the amount of this impact is always a stumbling block to bridge engineers, as shown by the number

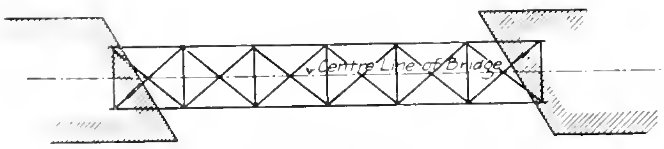

Fig. 7.—Right-Handed Skew, Showing Bridge With Ends Square.

of different formulae in use. The intensity of this impact depends on the length of span under load, the proportion of dead and live loads, the elasticity of material and other causes which are unknown, and it is imperative that practical experiments be made on all types of bridges to determine a formula for impact which will be reasonable and satisfactory. However, all formulae used at present are doubtless on the safe side.

The wind stresses in an ordinary plate girder span do not affect the sections of the main girders at all, because they are usually not considered unless they exceed 25% of the other loads combined. In plate girder bridges a moving load of 600 pounds per lineal foot of span is ample to provide for the wind on a moving train, for the oscillation of the train and for the wind on the bridge itself. This force will determine the wind stresses in the lateral system.

The centrifugal force of a train, when the bridge is on a curve, is not so important as the preceding stresses, but it cannot be neglected and should be considered, both in the laterals and in the main members. The equation $F = \frac{W V^2 D}{85700}$ gives the centrifugal force for a load W on a curvature of D degrees with a velocity of V miles per hour. It is considered to act in a horizontal direction, five feet above the base of rail and at right angles to the line of bridge. All engineers agree that the force F must be resisted by the lateral bracing in the same manner as the wind stresses, but they do not all have the same opinions of the stresses produced in the main girders. The best arrangement of a curved track on a bridge, is to place the axis of the bridge parallel to the chord of the curve, and to make the centre line of the bridge bisect the middle ordinate of the curve at the centre of the span. In other words, the deviation of the track from the centre line of the bridge is the same at the middle as at the ends of the span, and this is an advantage in the event of train derailment. Some bridge engineers are satisfied to consider that, with this position of the track, there will be practically the same load on both girders, and they only add centrifugal force stresses to the lateral system, and use the same girders for a track on a curve as for a track on a tangent.

A more general practice is to assume that there is an overturning action, and that in addition to one-half the live load, there is a load on the outer girder equal to $\frac{F h}{b}$, where F is the centrifugal force, h is the height at which F acts above the lateral system, and b is the spacing centre to centre of girders.

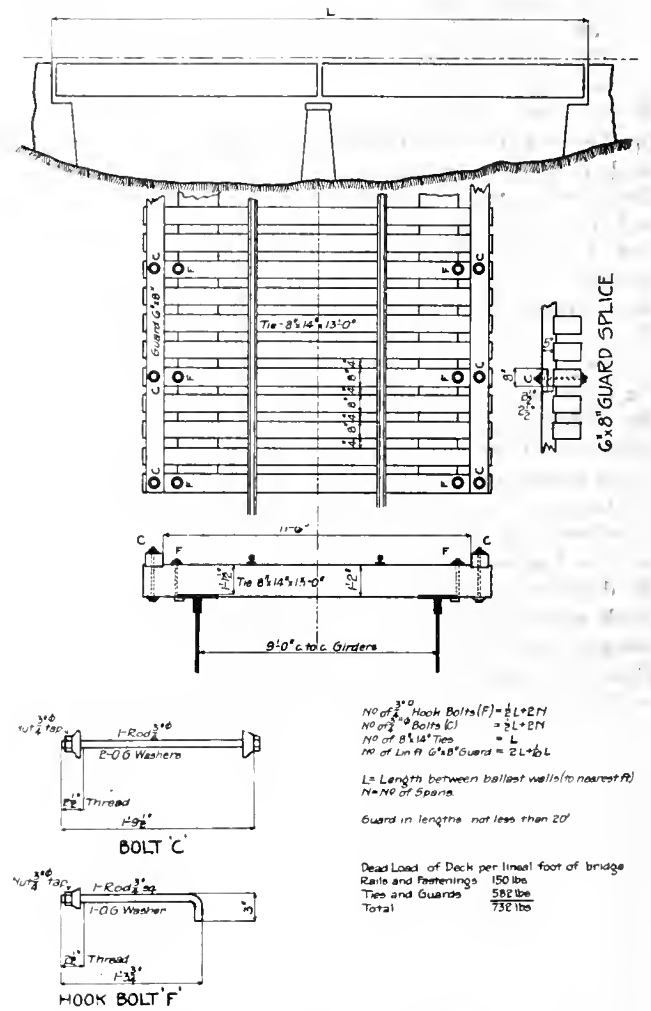

Fig. 8.—Standard Floor for Deck Bridges—Without Steel Floor Beams and Stringers.

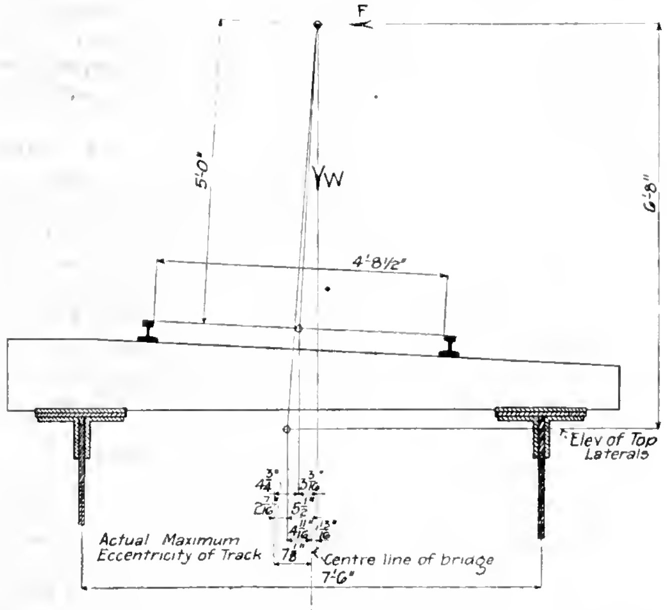
Another practice is to consider that the eccentricity of the track at the centre of the span is constant over the entire length of the bridge. Then the proportion of the live load to be added to each girder is given by the formulae $W\left(\frac{M + b}{2 b}\right)$

Where W equals the live load, M is the centre ordinate to the curve, and b is the distance centre to centre of main girders. A thorough treatment of this subject is given in Fig. 9 and the data accompanying it. The theory applied in this example was advanced by Ward Baldwin, who is a college professor and a practical man, and perhaps the best authority on this subject in the United States. He was consulting engineer on a large viaduct in Cincinnati, which the writer designed. In this example the track is super-elevated to suit only a medium speed of train. On account of this arrange-

ment, neither the vertical direct load of a stationary train, nor the direction of the resultant force of a train at high speed, pass through the centre line of track, and these conditions are all taken care of in the calculations. Mr. Baldwin also finds the centre of gravity of the segment, and uses it as the effective position of the centre of the track throughout the length of the span for deck girders. He then arrives at the effective eccentricity for either a fast or slow moving train. The worst condition is used in the calculations, and both girders are made the same section. The extra load which is figured to come on one of the main girders is given as a percentage of the applied load. It is used in the stresses



Length of Chord = Overall length of Girder = 62'-0"
Arc = 62.06 ft Radius 406.424 ft
½ Versine = $7\frac{1}{8}''$ Elevation of Outer Rail = 3"
C G of Arc from vertex $\frac{.06}{62.06} \times 406.424 \times 12 = 4\frac{3}{4}''$
Required Eccentricity for Equalized Stresses, train standing $3\frac{3}{16}'' + 4\frac{3}{4}'' = 7\frac{15}{16}''$
Velocity of Train 30 feet per second
F = ·0688 W Couple due to F = ·0688 W x 80" = 5.504 W
Eccentricity due to F = −5½"
Required Eccentricity, train moving $= 7\frac{15}{16}'' - 5\frac{1}{2}'' = 2\frac{7}{16}''$
Actual Eccentricity = $7\frac{1}{8}''$
Effective Eccentricity, train moving $4\frac{11}{16}''$
Effective Eccentricity, train standing $\frac{13}{16}''$
Train moving, outer girder has excess $4\frac{11}{16}/90 \times W = 10.42\% \frac{W}{2}$
Train standing, inner girder has excess $\frac{13}{16}/90 \times W = 1.8\% \frac{W}{2}$

Maximum Bending Moments	Live Load	1,950,000	3,169,000
	Impact	1,219,000	
	Eccentricity	10.42%	330,000
	Dead Load		458,000
	Total		3,957,000

Assumed Loading L L Coopers E60
D L 1017 lbs per lin ft of Girder

Fig. 9.—Distribution of Loads for Bridges on Curves.

in connection with the live load plus the impact. The above method of determining the centrifugal force stresses, combines all the assumptions made by other engineers, and suggests new ideas which merit consideration. It was the first time, so far as the writer knows, that it had ever been used and it is the more interesting on that account.

The same theory applies in the calculations of the floor system and girders of through spans, with the exception that the position of the centre line of the track at the various panels is used in the calculations, and it is not necessary to assume an effective position of the track over the length of the bridge. In through bridges, too, the stringers should be made to follow the line of track as near as practicable.

When the track is on a spiral, the degree of curvature at the centre of the span is considered constant over the whole length of the bridge in figuring the centrifugal force.

The traction stresses are caused by the momentum of trains either starting or stopping, the amount being dependent upon the coefficient of friction between the wheels and the rails, which is usually considered .20. This force is not considered in connection with the main girders at all, but it does affect the lateral bracing in through plate girder spans. The best construction, to provide for this force, is to connect the bottom of the stringers to the lateral angles at the points where they cross, and to add a diaphragm between the stringers at these points, which will take the resultant of the stresses in laterals and stringers. This diaphragm will also act as a lateral support for the top flange of the stringers. The reason for the above detail is to prevent the traction from producing any horizontal bending moment in the floor beams.

NEW RECORD FOR GREAT LAKES.

A contract has been awarded by Montreal interests to the Western Drydock and Shipbuilding Company at Port Arthur for constructing the largest freight-carrying vessel ever built on the Great Lakes. It will have a capacity of 450,000 bushels of grain. Its length will be 625 feet; width, 59 feet; depth, 32 feet, with bulk-freight pattern, engines of latest type and of sufficient power to lead in speed, and Isherwood construction system, with five bulkheads, thus dividing the ship into six compartments. Work will commence this month and the vessel is to be ready for the 1914 season, operating between Port Arthur, Fort William and Collingwood, Ontario.

VANCOUVER HARBOR PROPOSAL.

The report of inspecting engineers on the feasibility of converting the harbor of Greater Vancouver into a strategic war base has been favorably considered by the British Admiralty in conjunction with representatives of the Canadian Government, according to the Manchester Guardian. The great increase in general shipping which is expected to take place at Vancouver renders it desirable that adequate measures for its protection should be taken without undue loss of time, and it is understood that when the permanent naval policy of Canada is announced a statement will also be made on the Pacific Coast defences of the country. There is already a naval base at Esquimalt, to the south of Vancouver Island, which possesses an admirable harbor with large docks and fortifications. The Government also have under consideration the question of establishing a naval base at Port Nelson, which is to be the tide-water terminus of the Hudson Bay Railway, a project that is to open up direct communication between Liverpool and the northwest of Canada, and to effect a saving in distance of 1,800 miles over the existing routes via Montreal, St. John and New York. Owing to this great natural advantage and to the fear, lately emphasized by the Canadian Minister of Public Works, that grain passing through the warm, humid climate of Panama would be in danger of heating, it is expected that vessels trading by the Hudson Bay route will have an immense advantage over those using the Panama Canal, and that in consequence the shipping interests of Port Nelson will rapidly develop.

WATER REQUIRED BY A STEAM RAILWAY SYSTEM.

In a report to the Illinois Water Supply Association, Mr. C. R. Knowles, general foreman of the Waterworks Department of the Illinois Central Railway, places emphasis upon the importance of an adequate supply of water of good quality for the maintenance of an economic and uninterrupted train service.

Not many years ago, the load of freight trains ranged from three hundred to five hundred tons, and an engine tender with a water storage capacity of twenty-five hundred gallons was considered ample: but to-day freight trains on important trunk lines of low gradients are loaded with two thousand to four thousand tons, and engines with tender storage capacity of nine thousand gallons are quite common. The consumption of water has, therefore, greatly increased and it has become necessary to raise the standard of water supply, both in quantity and in quality in order to meet the traffic conditions.

In former years it was the practice to erect a tank and establish a water station at any point where water of any kind was most convenient, with little regard for quality or future requirements. This has necessitated many changes to meet the changing conditions and added requirements, relocating the water stations with due regard to curvature, gradients and the many previously unknown expedients of operation.

To accomplish the desired result it is often necessary to pipe water from a considerable distance, or, if an ample supply is not otherwise available, to sink wells, or construct an impounding reservoir. If the available supply is not satisfactory in quality, it is often necessary to erect treating plants for converting it into a suitable water for locomotive purposes.

All these changing conditions and increased requirements have made it necessary to maintain a waterworks department organization, whose duties are similar to that of a city waterworks department. Constant vigilance on the part of this organization is necessary to maintain an uninterrupted supply of water at all times.

The amount of water required by a railroad 6,500 miles long, over the entire system, for all purposes, is approximately 16,500,000,000 gallons per annum.

Only part of the water consumed is metered, as a large part of it is furnished on a flat rate, or pumped by facilities, owned and operated by the railroad; consequently the figures given are estimated, the estimates being based on comparative figures at points where meters show the actual amount used.

The consideration of first importance in railway water supply, both in quantity and in quality, is water for locomotives. A water which would be ideal for this purpose would be one that would not scale, would not corrode, and which would not foam or prime. Unfortunately nature does not supply such a water; consequently, where these evils do not cause too much trouble they are tolerated and where they are excessive the water is treated. In the State of Illinois, on 2,000 miles of railroad, locomotives consume annually 4,236,838,000 gallons of water; 1,751,790,000 gallons of the above amount is purchased from municipal and privately owned waterworks plants, and 138,645,000 gallons is treated by purifying plants owned by the railroad company. It is necessary to maintain 123 water stations to distribute this water to locomotives at required points.

The washing and filling of locomotive boilers at terminals require a large amount of water in addition to the above, which amounts to approximately 950,000,000 gallons per annum. This is, of course, supplied through the same facilities supplying water for locomotives, with additional facilities for maintaining the desired pressure for washing and the necessary pipe lines for distribution of the water under pressure.

There is also the consumption of water by stationary power plants, including water used for condensing engines, which is approximately 300,000,000 gallons per annum, 125,000,000 gallons of this is city water. Water is also used for sanitary purposes at shops, roundhouses, offices and stations. This requires an additional estimated amount of 250,000,000 gallons, 200,000,000 gallons of which is city water. The grand total is 5,736,838,000 gallons used for all purposes in Illinois alone, 2,476,790,000 gallons of this is purchased from city plants.

It is interesting to note that forty-three per cent. of the water used in the State is purchased from municipal or private waterworks. It would seem that the railroads of the State form such a large portion of the various water companies' patronage that rates for water purchased from city plants could be made sufficiently attractive to secure even more of what would appear to be very desirable business. As a matter of fact the city rates in a great many instances are so high that the railroad companies wherever it is possible to do so have found it cheaper to install and operate their own stations.

The use of superheaters on locomotives, and modern washout plants, where the water is blown off from locomotives into the washout system and used again for washing and heating fresh water for refilling, have affected economies in the use of water, but the consumption of water has increased to such an extent on account of the larger business being handled that the result of these economies is not perceptible in the grand total of water consumed.

A great deal more might be said on this subject, but costs, merits of various sources of supply, methods of pumping, treatment and filtration have not been considered in detail, the object being to present the water supply of a railway system only in a general way.

ROYAL COMMISSION OF GEORGIAN BAY CANAL.

A Royal Commission will be appointed to investigate the commercial advantages of the Georgian Bay Canal project. Whether the Government will proceed with a twenty-two foot waterway from Montreal through to the head of the lakes via the Ottawa River and the Georgian Bay, or whether it will proceed to deepen the St. Lawrence Canal to a depth of twenty-two or possibly thirty-five feet will depend upon the report of the Commission.

One of the two or three interior terminal elevators to be erected by the federal government in the Canadian West is to be in Calgary. Placed as this city is at the natural gateway from the grain growing area of Alberta and Saskatchewan to the Pacific coast and the Panama Canal, no other decision seemed possible. The Grain Commissioners voiced their disapproval of the city's laissez-faire attitude in not presenting a more elaborate case when the question was under consideration, but to Calgarians, the situation is so apparent that the organizations most particularly interested may be excused for thinking that everyone else ought to see it as plainly as they.

SOME THERMAL PROPERTIES OF CONCRETE.

By Charles L. Norton, Mem.Am.Soc.M.E.

A few of the results of a series of experiments carried on at the Massachusetts Institute of Technology, during the past four-and-a-half years, formed the subject of a paper read by Prof. Norton, at a meeting of the American Society of Mechanical Engineers, in Boston, on February 25th. The purpose of the research was a study of the physical properties of Portland cement concrete, which affect its value as a fire resistant material. The experiments had not been completed, but there was much of interest in what had been already ascertained.

It was proposed at the outset to make a study of the various physical properties of Portland cement concrete over as wide a range of temperatures as possible, and among the properties were the following:—

a Coefficient of linear expansion
b Diminution of mechanical strength after heating
c Specific heat.
d Coefficient of thermal conductivity

A comparison with other materials was also planned.

Coefficient of Linear Expansion—The measurements of the coefficient of linear expansion are now practically completed. The method adopted for the measurements of elongation caused by heating was the common so-called telescope method. The specimens in the shape of 6-in. or 10-in. cubes were slowly heated in a double gas muffle or an electric resistance furnace. The temperature of the furnace and of a number of points in the concrete was taken by means of platinum-rhodium couples. Near the furnace were mounted two telescopes, which could be sighted through holes in the furnace wall upon reference points on the surface of the block. At low temperatures an arc light and system of mirrors were used to furnish adequate illumination. One of the telescopes was provided with a micrometer eye-piece by means of which a movement of the reference mark of 0.0001 in. could be measured.

The values obtained at low temperatures agree very well with the commonly accepted value of 0.0000055 for the elongation per unit of length per deg. Fahr. Apparently, this value increases slightly up to 575 deg. Fahr. Above this point the coefficient becomes smaller; at 1,500 deg. Fahr. the coefficient becomes zero, and above this point, slightly negative.

Table 1 gives the average values for a large number of specimens:—

Table 1 Average Value of Specimens.

Temperature, Deg. Fahr.	in the Expression $l_t = l_o \ (1+\beta t)$
72 to 360	0.0000045 to 0.000060
72 to 750	0.0000050 to 0.000060
72 to 1090	0.0000045 to 0.000050
72 to 1600	0.0000035 to 0.000042

The blocks which have been heated to 1,500 deg., did not return to their original dimension on cooling, their permanent elongation being about 75 per cent. of their maximum elongation. There was no sensible permanent elongation resulting from a second heating.

All of the specimens tested for expansion were of stone concrete of the proportions 1 : 2 : 5. The stone was clean, the sand sharp, the cement of good quality, and every precaution was taken to secure a concrete of the first order. The specimens weighed on the average 150 lb. per cu. ft. A considerable number of tests demonstrated that the dimension which these small cubes took during a rise in temperature was dependent upon the temperature of the outside rather than the average temperature of the block.

The variation of this coefficient with the temperature is such as to make the difference between it and the coefficient for steel considerable at high temperatures. As has been well understood, the similarity of the coefficient is helpful in preserving the integrity of reinforced concrete structures at ordinary temperatures, but the divergence of the two coefficients at higher temperatures is not a serious matter in the reinforced structure when exposed to fire, since the metal reinforcement and the concrete surface are rarely at the same temperature.

There is a marked expansion increase up to about 700 deg. Fahr., followed by a slower rate, and at about 1,500 deg. Fahr. by marked shrinkage.

Comparison with Clay Brick and Silica Brick.

	Clay Brick	Silica Brick
Temperature Range, Deg. Fahr.	Coefficient of Expansion (β)	
0 to 900	0.0000038	0.000012
0 to 1600	0.0000031	0.000008
0 to 1900	0.0000023	0.000007

Some bricks and all concrete are liable to a permanent set of about 75 per cent. of their total elongation on heating to 1,500 deg. Fahr.

Diminution of Mechanical Strength after Heating—In order to study the effect of high temperatures upon the compressive strength of concrete several scores of 6-in. and 8-in. cubes were made and allowed to set for 90 days or slightly longer. These blocks were heated at different temperatures in a gas furnace similar to that used for the expansion experiments, for different lengths of time at various periods from the 90 days up to five years.

The cubes which were not heated showed an average compressive strength of 2,700 lb. per sq. in. when 90 days old; at the end of five years the compressive strength of the blocks had risen to an average value of 4,278 lb. per sq. in. When aged for 90 days in a damp place, exposed to fire at 900 deg. Fahr. for two hours, the compressive strength fell to 2,200 lb., or a loss of 15 per cent. Blocks five years old, dry, exposed to fire at 1,700 deg. Fahr. for two hours, gave values of 1,500 to 1,000 lb. per sq. in., a loss of 50 per cent. to 65 per cent.

The loss was much more marked in the case of the 6-in. than the 8-in. cubes. It is evident that the small cubes give far too great loss in strength on heating. Some cubes allowed to stand lost much by slacking; this action has been noted by Professor Woolson in earlier tests. It should be noted also that there was a considerably greater deformation under load of the heated blocks than of those not heated.

A large number of small beams were next made, some with and some without reinforcement; most of these were either 6 in. by 6 in. by 48 in. or 8 in. by 8 in. by 48 in. The specimens which were reinforced contained four ½-in. round steel rods situated near the corners equidistant from the two faces of the beam. In some the distance from the reinforcement to the face of the beam was 1 in. and in others 1½ in. A few beams had a 2-in. protection to the reinforcement.

Three beams for example, each 6 in. by 6 in. by 48 in., in which the reinforcing rods were 1 in. from the face of the beams, were broken by center load, the first beam not having been heated at all, the second heated for one hour in a fire that fused the surface of the concrete, and the third being similarly heated for two hours. The beam which was not heated broke under a load of 5,700 lb., the second, heated for

one hour, broke at 2,750 lb., while the third, heated for two hours, broke at 1,950 lb. This is a most remarkable showing under severe conditions. It should be borne in mind that these small beams were so slow in cooling down that they showed the effect of heating much longer than the time mentioned, say 24 hours. The flames, moreover, surrounded the beams on all sides. In tests at three and five year ages, the temperature was between 1,600 deg. and 1,700 deg. Fahr.; the 8 in. by 8 in. by 48 in. reinforced beams broke at 14,200 lb. when not heated, but at 4,920 lb. when heated. Smaller beams 6 in. by 6 in. by 48 in., not reinforced, broke at 1,300 lb. when not heated, at less than 100 lb. heated.

As a result of these tests upon the beams, it was evident that the failure of the specimens was in every case due to the rods pulling through the concrete. This is wholly a matter of insufficient anchorage, and these short beams are therefore not very helpful in giving information concerning the behavior of full-sized beams in buildings, and except as they give relative information concerning different mixtures, they are of very little value. The small cross-section of these beams tends to make the fire exposure abnormally high. It should be noted that all of the non-reinforced beams broke in handling, which suggests the severity of the tests as compared with the experience of actual conflagrations.

A series of similar beams was next made up of cinder concrete, the proportions of the mixture being 1 : 2 : 5. A portion of these were mixed with clean cinders, which showed upon analysis but little carbon; a second part was mixed with cinders to which 10 per cent. of fine bituminous coal had been added and the other beams were mixed with cinder, to which had been added 25 per cent. of fine coal. The 25 per cent. mixture can be disposed of in a word—when once thoroughly heated it burned until it fell to pieces. With the 10 per cent. mixture, however, no such action occurred; there was no indication that the concrete would support its own combustion even for a short time. It was apparent, however, that the 10 per cent. mixture was not so good a fire-resistive material as that which contained no added carbon. From the few specimens containing less than 10 per cent. which have been examined up to the present, it seems probable that the safe limit is close to 5 per cent. More information is now being secured on this point by the use of larger beams.

Specific Heat—The study of the specific heat of concrete was made by the ordinary calorimeter method, the "method of mixtures" of Regnault. Specimens of the concrete, usually fragments of the larger test pieces, were heated slowly in an electric resistance furnace to the desired temperature and then plunged into the calorimeter. The weight of the water and its rise in temperature give the amount of heat given off by the body in cooling. Extraordinary precautions were taken in getting the exact average temperature of the specimen in the furnace, and to insure its rapid transfer to the calorimeter. In most of the experiments a double calorimeter was used so that the specimen did not come in contact with the water of the calorimeter, so that any evolution of heat by hydration of the cement was avoided. Tables 2 and 3 give the specific heat of concrete and of other materials:—

Table 2—Specific Heat.

Coefficient of Thermal Conductivity.—The measurements of thermal conductivity were made by a number of methods and have taken far more time and energy than all the others put together. The thermal conductivity is that property which determines how rapidly heat will travel through a substance and how rapidly therefore objects beyond will be heated by transmission. The conductivity becomes of prime importance in all questions of protection of the metal in reinforced concrete buildings. There is a limited amount of data to be found relative to this important property of any of the common materials of engineering and such data as are to be found are not concordant. As to the conductivity of concrete or its variation with temperature and with composition, practically nothing has been known.

The methods adopted for the measurements will be here described in outline only. The formula showing the relation of the temperature upon the two sides of a plate to the amount of heat which would flow through is as follows:—

$$Q = \frac{K\ (t_1 - t_2)\ sA}{d}$$

$$\text{or } K = \frac{Qd}{(t_1 - t_2)\ As}$$

where

K = the coefficient of thermal conductivity dependent upon the nature of the material and its temperature.

Q = the quantity of heat flowing through the plate in the area measured

A = the area

t_1 = the temperature of the hotter side of the plate

t_2 = the temperature of the cooler side of the plate

d = the thickness of the plate

s = time during which Q units flow through the area A.

The formula will be seen to be merely an expression of the following relations, that the flow of heat is proportional to the area, to the temperature and to the time, and that it is inversely proportional to the thickness.

After spending many months in attempting to develop other methods, the electrical method used by the writer for the past 15 years in studying the flow of heat through steam

pipe coverings was adopted. The value Q of the heat flowing was determined by supplying the heat by means of the heating of a conductor carrying a current of electricity; by measuring the electrical energy supplied the quantity of heat developed may be known with great precision. Further, if this heat is passed through the plate under test and into a calorimeter on the far side, a check upon the value of Q may be had. For the determination of the temperature difference, thermal couples, resistance thermometers, and mercury thermometers were used, but thermal junctions made of thin strips of copper and nickel, or of platinum and platinum-rhodium, were generally found most serviceable.

The apparatus used for the lower temperatures consisted of a thin, electrically-heated plate, to the two sides and edges of which concrete could be applied. Outside of the concrete there were then placed heavy copper or brass plates which could be kept at a constant temperature by an internal circulation of water. Thermal junctions were placed at several points on each surface and in the body of each concrete plate. The electrical input was measured by calibrated Weston instruments, and calibrated thermal junctions gave the value of the temperature difference to the nearest one-one hundredth of a degree. For the thickness, numerous measurements were made with a pair of flat-nosed calipers and averaged. It was necessary to keep this apparatus running for several days before it could be balanced, that is, before the rate of flow of heat outward through the plates became constant and equal to the electrical input.

Later, in order to make tests on plates as thick as some of the walls in common use, another method was adopted. Cubical boxes 36 in. in outside dimension were built with walls of several thicknesses. Inside the boxes were placed electric heaters which served to raise the inside surface to a temperature above that of the surroundings and a small fan served to keep the air in the box stirred to insure uniformity of temperature throughout. The boxes were tightly sealed. The power supplied to both heater and fan was measured as before. Mercury thermometers and thermal junctions, as well as a Callender recording resistance thermometer, were used to measure the difference in the temperatures inside and outside of the box.

Data have been secured on scores of specimens and they are practically identical with the results obtained by the plate tester. It must be borne in mind that the thermal conductivity is based upon the difference in temperature at some two points in the material itself and not the difference in the temperature of the air on the two sides of the specimen. If, for instance, a 6-in. wall of solid stone concrete separates two spaces whose temperatures are 40 deg. Fahr. apart, the surface temperatures of the concrete will be much nearer one another than 40 deg. Fahr. There is a drop in temperature in passing through the wall which is dependent upon the thermal conductivity and upon the quantity of heat passing through. There is a drop in temperature at the surface which is dependent on a rather complex set of relations between the temperature and nature of the surface and the surroundings and the adjacent air. For many materials the amount of heat lost from a surface for small differences in temperature not over 20 deg. Fahr. is between 16 and 18 B.t.u. per sq. ft. per 24 hours for 1 deg. difference between the surface and the average temperature of the surroundings. More than one-half of this is a loss by radiation in accordance with the Stephan-Boltzman law.

$$\text{Energy} = \text{Constant}\ (T^4 - T_0^4)$$

$$W = 5.7\ E\left[\left(\frac{T}{1000}\right)^4 - \left(\frac{T_0}{1000}\right)^4\right]$$

where

W = watts

T = absolute temperature of surface

T_0 = absolute temperature of surrounding.

E = about 0.6 to 0.7 (always less than 1)

For the high temperatures a modification of the entire process was found necessary. The concrete to be tested was cast in the form of a cylinder on the outer surface of and concentric with a steel bar which could be heated to a high temperature by the passage of a heavy current. Outside of the cylinder of concrete was applied a closely fitting "continuous" calorimeter. The temperatures of the bar and of the calorimeter were measured by thermal junctions, and the amount of water and its rise in temperature gave the value of Q. In order to guard against the uncertainty of the temperature at the ends of the bar, the calorimeter was made so as to enclose only about one-half the length of the bar, the rest being covered by guard rings similar to the calorimeter, but without provision for the measurement of the quantity of water.

The heating of the bars required a considerable amount of special apparatus, since it was necessary to provide a current of upwards of 2,000 amperes for the high temperatures, and to be able to vary its amount to any desired value below that point. For this purpose there were installed three 15-kw. transformers connected on the primary side with a three-phase 2,300-volt circuit. By means of divided secondaries and a rather elaborate arrangement of switches, the secondary voltage could be varied from 190 volts down to 55 volts. This secondary voltage was applied to the primary of a second step-down transformer, whose secondary was divided into 20 coils. By means of a switchboard the entire output of the transformer could be had at almost any desired low voltage. This enabled us to heat bars insulated by materials of different composition and of different thicknesses to any desired temperature up to 2,800 deg. Fahr. With this arrangement both the steel and the concrete can be easily melted.

The results obtained are given in Table 4. It is to be regretted that there is no uniformity of practice as to the units to be adopted in reporting the measure of effectiveness of insulators. While the physicist renders his report in calories per square centimeter, per centimeter thickness, per one degree centigrade per second, the steam engineer confines his observations to B.t.u. per hour, per square foot, per inch of thickness, per one degree Fahrenheit, and the refrigerating engineer reports on the basis of a 24-hour time unit. The

Table 4—Coefficient of Thermal Conductivity of Concrete.

Temperature of Hot Side of Plate Deg. Cent.	Deg. Fahr.	Mixture	Coefficient, Cal. per 1° C. per sq. cm. per cm. per sec.	Coefficient, B.t.u. per 1° F. per sq. ft. per in. thick per 24 hours

1100	2012	Stone 1—2—4	0.0029	202.

writer has even seen a report in terms of hogsheads of water raised to the boiling point, time not stated. A brief comparison of these values with those for other materials may be interesting.

The specific heat of concrete is slightly less than that of either red brick or fire brick, hence the amount of heat needed to raise the temperature of a pound of brick is about 10 per cent. more than for a pound of concrete. But the density of concrete is enough greater than that of brick to raise

the heat capacity of a cubic foot of concrete above that of brick. The difference is not large, however,

It seems clear that for a time after the beginning of exposure to fire, the concrete and its reinforcement will expand at much the same rate, but that the further expansion of the surface will not proceed at so rapid a rate. This will tend to reduce the stresses which the expansion of the heated surface would otherwise set up in the cooler interior. It is perhaps because of the failure of the concrete to return to its original dimensions that the small amount of surface cracking found after a fire is due.

The experiments made with coal and cinder mixtures indicate the necessity of added care in the selection of cinders for this purpose.

Table 4 of thermal conductivities gives data as to the rate at which heat will travel through concrete. It is interesting to note the great difference between the tamped and the untamped concretes made from stone. The one was as porous as possible, and the other as dense. One transmits nearly twice as much heat as the other. The cinder concrete, as is commonly believed, is much better as a heat insulator than the stone concrete, being nearly three times as effective as the denser stone concrete in retarding the flow of heat. It may be interesting to call attention to the heat insulation afforded by other materials. The best of the commercial articles commonly used for this purpose is compressed cork, which is nearly 25 times as effective as stone concrete. Steel on the other hand, transmits heat from 75 to 100 times as fast as the densest of the stone concrete.

Table 5—Thermal Conductivities..

Material	B.t.u. per 24 Hours per 1 Deg. Fahr. Sq. Ft. per 1 In. Thick.
Agglomerated Cork	6.4 to 9.0
Linings or Quilts of Hair and Flax	10.0 to 18.0
Pine	13.0
Oak	26.0
Spruce	14.0 to 18.0
Magnesia	10.0
Asbestos Sponge	8.0

STEEL BRIDGE PROTECTED WITH CEMENT.

The Department of Public Works in Pittsburg has recently made use of an ingenious method to save from deterioration a footbridge on Pine Street that passes over the railroad tracks. This steel frame was becoming affected by the gases from the engines that passed beneath it. In order to save the bridge from ruin the board enclosed it in concrete, which was so attractively and effectively set in place that the bridge is now stronger and far more artistic than ever, and at the same time is protected from any further attacks by the deleterious fumes. The entire structure, including the stairways, the supports, the floor and railing, were covered with a layer of cement, and the viaduct is now a reinforced concrete structure, although such a thing was not contemplated at the time of its erection. The idea is so practical that it may be worth following elsewhere in the case of metal structures of various kinds that are subjected to disintegrating gases.

Escher Wyss & Company have moved their head Canadian office from the Canadian Express Building to the Coristine Building, Montreal.

HIGHWAY CONSTRUCTION WITH PAINT BINDER AND ITS SHEET ASPHALT SURFACE.

A type of construction not generally used in the building of interurban roads is being employed on one of the roads of the state highway system of California on the section lying between South San Francisco and Burlingame. The most unusual features of the construction are the thin asphalted binder coat, and the 1-in. sheet asphalt surface. The following description of the work on this section is abstracted from an article by Mr. A. E. Loder, division engineer, in the California Highway Bulletin, the official publication of the State Highway Commission:

The roadway is graded to a width of 40 ft., with a maximum gradient of 4 per cent. conforming with the rolling contour of the country. Long, easy, vertical curves connect all changes of grade, producing a pleasing profile. Flat curves are used at every deflection in the line.

The pavement is 24 ft. in width and has a crown of 4 ins. Earth shoulders containing gravel and old macadam extend to a width of 8 ft. along each side of the pavement with a cross slope of 1¼ ins. per foot. The pavement rests upon a thoroughly compacted sub-grade composed of old macadam and a sand-clay mixture resembling hardpan, which after rolling is in such condition that it is not damaged when the gravel and sand are hauled and dumped directly upon it without the use of planking, and it remains so compact that no dirt is picked up with the sand when loading it into the mixer.

Timber headers 2 ins. by 6 ins., nailed to stakes, line the pavement trench and are laid to a line flush with the finished surface. These protect the edges of the pavement while the shoulders are being settled by traffic, and provide a means by which the pavement may be readily brought to a true and uniform surface.

The pavement consists of a 5-in. concrete base composed of a 1:3:6 mixture, to which is bounded a standard sheet asphalt surface 1 in. in thickness.

The concrete is prepared in a portable mixer to a rather wet consistency and is delivered directly to its place in the pavement by means of a swinging spout. The surface is given a rough finish, suitable for binding bituminous materials, by sweeping across the line of pavement with a stiff house broom or warehouse broom before the concrete reaches its final set. The new concrete is watered daily, except in rainy or damp, cloudy weather, until about five days old.

The asphalt wearing surface being laid on this job is shown on the daily test sheets to be as near the standard grading and composition as is possible to obtain. Nothing unusual is noted in connection with its use, except that a greater density is obtained after rolling the one-inch sheet than is possible with a thicker city surface, and consequently better wearing qualities and more stability should be expected.

When the concrete is dry and at least one week old, it is thoroughly swept, removing the dust of traffic passing at the side of the road. The binder coat is then applied. This coat consists of 1 part by volume of melted asphaltic cement, of the consistency used in the pavement, to 2 parts by volume of engine distillate. The asphaltic cement is heated in a small portable kettle to a temperature between 200° and 325°. A measured quantity is removed to the spreading pail a safe distance from the fire and allowed to cool to about 250°. The distillate is then added and stirred for about one minute, when it is found to be thoroughly uniform and the temperature is reduced by at least 100°. The distillate can be added when the asphalt is at a temperature of 325°, but at this tem-

perature it is accompanied by considerable boiling and is somewhat dangerous.

The binder liquor, while hot, is poured over the concrete from buckets, and uniformly swept over the surface with stiff house brooms until every particle of surface is coated with a thin film and all excess is swept from holes or depressions in the concrete. The paint binder penetrates deeper into the concrete when permitted to flow in a thin wave ahead of the first sweeping. A second sweeping after a few minutes removes excess from depressions and spreads it uniformly over the concrete. The thinnest possible application of paint should be used so that after evaporation, which is completed in from one and one-half to two hours, the surface should have a glossy black appearance. If too small a quantity is used, or if the percentage of asphaltic cement to distillate is considerable less than above, a brown surface will result, which will not make a successful bond with the asphalt surface.

Two men can easily mix and apply this asphaltic coat on 12,000 sq. ft. per day. On 69,000 sq. ft., where the proportions were being varied somewhat, it was found that 100 sq. ft. required 0.856 gal. of engine distillate and 3.5 lb. of asphaltic cement. The total cost on above area, including 15 per cent. on labor, was $0.0018 per square foot of surface.

It is found that no inconvenience is caused to the work of laying asphalt by the placing of the asphaltic coat. After one hour's time it does not stick to the wheels of motor trucks or wagons. It is not desirable to so cover the concrete farther ahead of the asphalt work than is required for the distillate to evaporate and leave the binder hard.

In one case, several days' rain which fell on paint freshly applied caused the asphaltic coat to appear loosened from the concrete in many places. After two days' dry weather, however, it seemed to bond again to the concrete so that it could not be removed. It is believed that the paint binder will tend to waterproof the asphalt surface, preventing damage to its under side from moisture which may rise through the concrete.

If the asphaltic coat is allowed to accumulate in any quantity in a depression such as a heel mark, its location is soon apparent after the placing of asphalt since excess asphaltic cement appears on the surface during rolling. With reasonable sweeping, however, no trouble of this kind has been experienced.

There is a marked difference in the behavior of hot asphaltic mixture under the roller where the paint binder has been used and where it has been omitted. Where concrete has been painted, the asphalt does not move or welt up in front of the roller to any appreciable extent, as is noted when rolling asphalt on plain concrete.

It is found that the asphaltic cement, while dissolved in the distillate, penetrates into the surface of the concrete to a distance of from 1/10 in. to ⅛ in. and in some cases even further. Samples of the surface removed show the concrete adhering uniformly to the asphaltic surface. When removing the sample the concrete is fractured and a layer of solid concrete is removed, carrying the first layer of finer gravel. When trimming a joint to begin a new day's work, the surface of the concrete base is always broken off in removing the thin edge of asphalt which has been cut from the finished work.

For experimental purposes, a few hundred feet of the surface has been placed without the use of the paint binder. As expected, no bond is secured except that of a mechanical nature, due to the roughness of the concrete. Notwithstanding this, the surface remains in first-class condition after one month of heavy traffic, and it is believed that good results will be obtained under wear without the use of a binder of any kind. However, the use of this binder at so small an additional cost will improve the pavement and prolong its life to such an extent it will more than justify its expense.

MAY FIRE LOSSES

The Canadian Engineer's estimate of Canada's fire loss during May amounted to $2,123,868, compared with April loss of $1,470,622 and $2,251,815 for the corresponding period of last year. The following is the estimate for May losses:—

Fires exceeding $10,000	$1,540,500
Small fires	306,342
Estimates for unreported fires	277,026
	$2,123,868

The following are the monthly totals of the losses by fire during 1910, 1911, 1912, and 1913:—

	1910.	1911.	1912.	1913.
January	$ 1,275,246	$ 2,250,550	$ 3,002,650	$ 3,913,385
February	750,625	941,045	1,640,153	2,037,386
March	1,076,253	852,380	2,261,414	1,710,756
April	1,717,237	1,317,900	1,355,055	1,470,622
May	2,735,536	2,564,500	2,251,815	2,123,868
June	1,500,000	1,151,150	4,229,412	....
July	6,386,674	5,384,300	1,741,371	....
August	1,667,270	920,000	1,164,760	....
September	894,125	1,123,550	883,949	....
October	2,195,781	580,750	1,416,218	....
November	1,943,708	1,506,500	1,184,010	....
December	1,444,860	2,866,950	1,769,905	....
	$23,593,315	$21,459,575	$22,900,712	$11,256,017

During May thirty-three lost their lives through fire; this is the largest number of fatalities since July, 1911.

The following are the monthly totals compared with 1909, 1910, 1911 and 1912:—

	1909.	1910.	1911.	1912.	1913.
January	16	27	27	27	14
February	8	15	12	11	21
March	16	20	18	24	22
April	18	37	20	15	11
May	21	15	28	18	33
June	16	52	13	6	..
July	4	15	110	9	..
August	17	11	22	16	..
September	10	10	13	6	..
October	26	16	17	21	..
November	34	19	20	22	..
December	33	19	17	28	..
Totals	219	256	317	203	101

The fire waste in each province for first five months of this year has been estimated by *The Canadian Engineer* as follows:—

Ontario	$2,697,806
Alberta	2,649,203
Manitoba	1,542,912
Quebec	1,109,266
Nova Scotia	943,409
New Brunswick	730,801
Saskatchewan	717,295
British Columbia	490,538
Prince Edward Island	374,787
	$11,256,017

CANADA'S MINERAL PRODUCTION.

The table on the opposite page is from the current issue of *The Monetary Times*. With the following explanation of symbols used, it should be of great value to all readers of *The Canadian Engineer*:—

*Short tons throughout. (*a*) The metals copper, lead, nickel, and silver are for statistical and comparative purposes valued at the final average value of the refined metal. Pig iron, zinc ore, and cobalt oxides are valued at the furnace or spot, and non-metallic products at the mine or point of shipment. (*b*) Copper content of smelter products and estimated recoveries from ores exported, at 12.376 cents per pound, in 1911; and 12.738 cents per pound in 1910. (*c*) The total production of pig iron in Canada in 1911 was 917,535 tons valued at $12,307,125, of which it is estimated 875,349 tons valued at $11,693,721 should be credited to imported ores; in 1910, the total production was 800,797 tons valued at $11,245,622, of which 695,891 tons valued at $9,594,773 are credited to imported ores. (*d*) Refined lead and lead contained in base bullion exported at 3.480 cents per pound, in 1911; and 3.687 cents in 1910, the average prices in Montreal and Toronto respectively. (*e*) Nickel content of matte produced value at 30 cents in 1910 and 1911. (Increasing quantities of nickel-copper matte are now being used in making monel metal which is sold at a price much below that of refined nickel.) The value of nickel contained in matte, as returned by the operators, was about 10 cents per pound for both years. (*f*) Estimated recoverable silver at 53.304 cents per ounce in 1911, and at 53.486 cents in 1910. (*g*) Gross returns for sale of gas. (*h*) Quantity on which bounty was paid and valued at $1.22½ per barrel in 1911 and at $1.23 in 1910. (*i*) Value received in 1910 by shippers of silver cobalt ores for cobalt content. Cobalt not paid for in 1911. (*j*) In 1910 includes 547 tons arsenical ore valued at $5,716. (*k*) In 1911, figures as reported by the producers, which differ slightly from those of the Trade and Navigation reports.

FITCHBURG SEWAGE DISPOSAL PLANT.

Points in the Design of Siphon and Grit Chambers of Main Interceptor—Settling Tanks and Sprinkling Filters are Also Special Features

In the fifth semi-annual report of the Sewage Disposal Commission for the city for Fitchburg, Mass., two interesting structural features of the main interceptor belonging to the new system were described. These are respectively the siphon and grit chambers. It will be remembered from previous articles that the commission was created in 1910 with authority to construct a main trunk sewer and a system of sewage disposal that would meet with the approval of the Massachusetts State Board of Health. The commission has Mr. David A. Hartwell as chief engineer and Mr. Harrison P. Eddy as consulting engineer.

Siphon Chamber.—The first section of the main interceptor is 5,989 ft. long. Of this distance 5,070 ft. is 30-in. cast iron pipe and 919 ft. is 48-in. concrete sewer. At the junction of the 48-in. sewer with the 30-in. cast iron pipe there has been constructed a siphon chamber, so arranged that when the flow in the sewer exceeds the capacity of the 30-in. siphon the excess will spill to the river through a 24-in. pipe line. The capacity of the 30-in. siphon is about 11,000,000 gals. per day, and as the present flow of sewage is only about one-half this amount it is only at times of considerable rain that anything from the sewer will flow through this overflow pipe to the river. The siphon is also

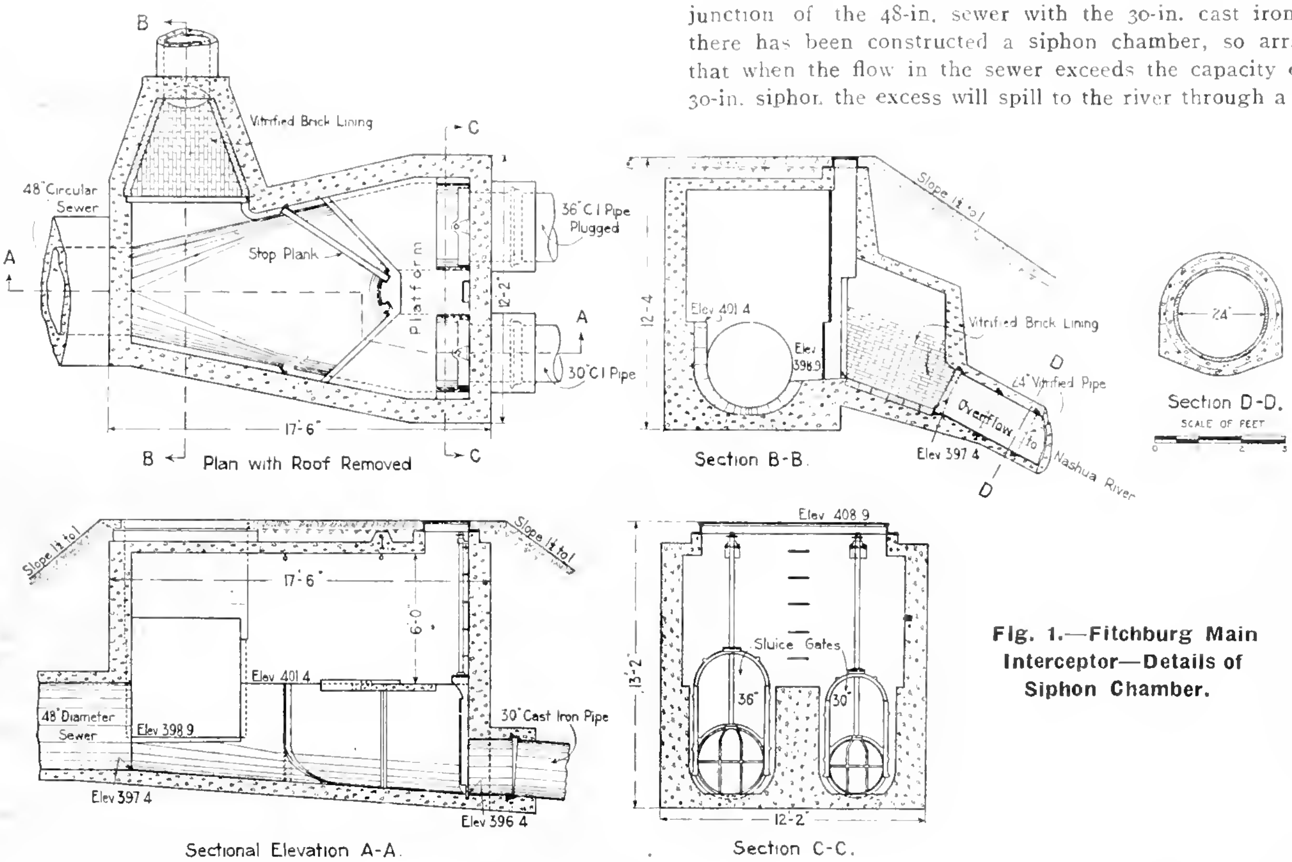

Fig. 1.—Fitchburg Main Interceptor—Details of Siphon Chamber.

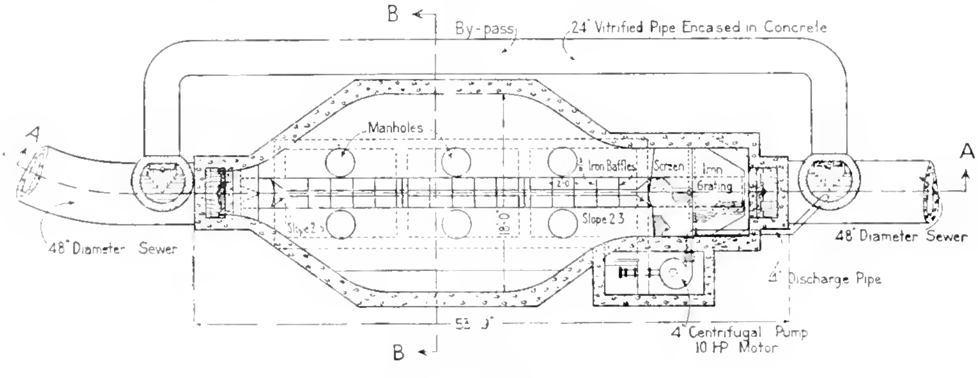
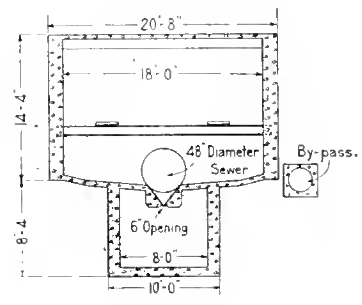
constructed with a 36-in. connection for an additional siphon pipe to be laid when the normal flow of sewage about equals the capacity of the 30-in. pipe. This overflow can be regulated by stop planks so that when the 36-in. pipe line is also laid no flow will be diverted to the river unless the amount flowing in the 48-in. sewer should exceed the capacity of both pipe lines. This siphon has a hydraulic grade of 1 ft. in 350 ft. When this 30-in. pipe is carrying the present amount of sewage the velocity of flow will be about 1½ ft. per sec., which would probably prevent the pipe from clogging if there were no gravel or sand carried with the sewage. To avoid possible clogging at time of storm a grit chamber has been constructed about 1,400 ft. above the siphon chamber, and between which and the siphon chamber there are no lateral connections. This grit chamber will be described in detail later. In case this siphon should become partially clogged provision has been made for blowing out the line by placing a 30-in. gate and blow-off pipe at the crossing of the river on land taken for the disposal area. This gate is so located and the siphon so laid that it will be completely and rapidly emptied when the blow-off gate is opened. The siphon chamber complete, as shown in Fig. 1, was built at a contract cost of $500.

Grit Chamber.—In all combined sewer systems there is at times of heavy rain considerable sand and gravel washed from the streets into the sewers. The catch-basins retain large quantities of this material but the rapidity of the flow through the catch-basins at times of heavy rains is such as to carry large quantities of mineral matter into the sewers. Before the sewage is treated in tanks at any disposal plant it is advisable to remove as much as possible of this mineral matter. This is done by grit chambers which are usually located near the disposal plant. Owing to the location of the long inverted siphon in the Fitchburg intercepting sewer with the lower end at the disposal plant it seemed desirable to construct the grit chamber above this siphon. Theoretically, the best location would be directly above the siphon chamber, but it seemed undesirable to build such a structure on private land if any other satisfactory location could be found. The location determined upon for this structure was in the sewer department yard about 1,400 ft. from the siphon chamber. While this grit chamber is located some distance from the siphon chamber still there will be no lateral connections with the sewer between the two. The general details of this grit chamber are shown in Fig. 2. The total length is 53 ft. 9 ins. and the maximum inside width is 18 ft. The sump or grit catcher situated below the sewer invert is 31 ft. 6 ins. long, 8 ft. wide and about 7 ft. deep. At the lower end of the sump is a pump well with a 4-in. centrifugal pump vertically connected with an electric motor with which to remove the water from the sump when it is desired to remove the sand and gravel settled from the sewage. The material collected in the sump will be removed in buckets through manholes provided in the floor and roof of the chamber. There is a 6-in. opening in the line of the sewer invert through the grit chamber floor the full length of the sump. Spaced 2 ft. apart there are placed in this opening iron baffle plates, the tops of which are of the same shape and at the grade of the sewer invert. These baffles are designed to arrest the flow of any mineral matter beginning to settle and divert it into the sump. The floor of the grit chamber was designed both in plan and section so that the velocity of the flow would be about 1 ft. per sec., no matter what volume was flowing in the 48-in. sewer. The table gives data relative

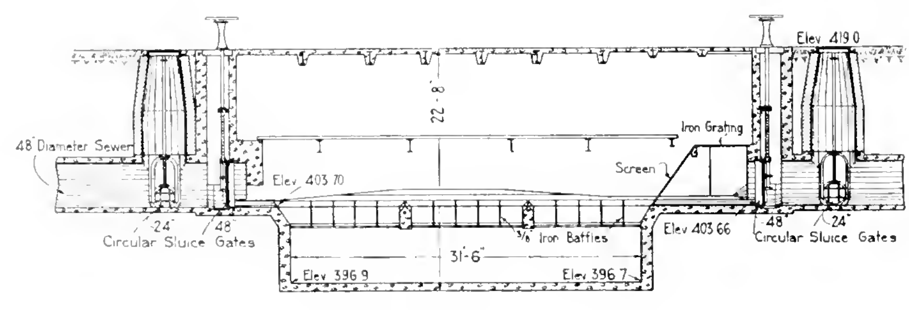


Plan with Roof Removed



Section B-B

Fig. 2.—Fitchburg Main Interceptor —Details of Grit Chamber.



Sectional Elevation A-A.

Flow and Velocities in Interceptor and Grit Chamber.

Flow	Gals. per day	Cu. Ft. Sec.	Depth in 4-ft. sewer.	Velocity in 4-ft. sewer.	Area of maximum water section in Grit Chamber.	Velocity in Grit Chamber.
1910 Minimum,	3,000,000	4.65	.92	2.06	3.99	1.17
1910 Average,	4,000,000	6.20	1.08	2.24	6.27	.99
1910 Maximum,	6,000,000	9.30	1.32	2.53	9.97	.93
1910 Storm	10,000,000	15.50	1.70	2.91	16.68	.93
1940 Average,	6,875,000	10.65	1.40	2.64	11.32	.94

Capacity of 4-ft. sewer with grade of .001 = 39.38 c. f. s.
Velocity of 4-ft. sewer with grade of .001 = 3.13 f.t per sec.
All above computations with n = .015 in Kutter's formula.

to velocities in the main sewer and grit chamber for the probable flow under conditions immediately following the completion of the present construction and also for the average flow of domestic sewage in 1940.

At the lower end of the grit chamber there is placed a screen so that any large matters in the sewage will be removed. This screen is made of 2-in. by ⅜-in. flat bars spaced 2 ins. apart on centres, making an opening between bars of 1⅝ ins. A 48-in. sluice gate is placed at each end of the grit chamber and a 24-in. by-pass constructed so that at times of removing grit from the sump the sewage will be carried around the chamber. This diverting of the sewage around the chamber will be only at such times as there is no storm water with the sewage. The grit chamber is roofed over at the surface of the ground with a concrete slab reinforced with I-beams and wire mesh. A small brick building for housing the electric motor and other equipment will be erected the coming season. This grit chamber was constructed by the International Construction Company, of Boston, at a total cost to the city of about $8,000.

The plans for the disposal plant have reached completion and bids were opened recently for the construction of settling tanks with separate sludge digestion chamber trickling filters, secondary settling tanks, etc.

Settling Tanks.—Sewage delivered to the works by the 30-in. cast iron siphon is first passed through a 30 x 15-in. recording Venturi meter and is then conducted to the battery of five Imhoff settling tanks. These tanks are built side by side and each is 90 ft. long, 30 ft. wide and has a maximum depth of 26 ft. As regards the inlet and effluent connections, both ends of each tank are identical in design, so that the direction of flow of sewage may be reversed periodically to equalize the sludge deposition on the tank bottom. The inlet to each tank consists of three 12-in. openings below the flow line, controlled by hand-operated sluice gates. The tanks are designed to afford a storage period of three hours, and the sludge-digesting compartment is sufficient for six months' accumulation. Under each gas vent is a sump for the collection of the sludge. Air pumps are to be used in its removal and the deposit will then be conveyed directly to the drying beds, while the settled sewage will leave the tanks over weir plates protected by scum boards, and will flow by gravity to the sprinkling filter.

The sprinkling filter, 2 acres in area, is in the form of a rectangle 410 ft. long and 228 ft. wide. The filtering material will consist of a 10-ft. depth of stone, crushed to a size of from 1 to 2 in. At one end of the bed is a main 36-in. cast-iron header to which 16-in. lateral distributing pipes are connected at intervals of a little less than 13 ft. Each lateral line is controlled by a valve, so that the area of the bed to be dosed with sewage can be varied to suit operating conditions. These lateral lines are reduced from 16 to 12 in. in diameter about half way down the length of the bed. The lateral distributors are supported directly upon the filter stones, in which they are buried to a depth which will bring the top of the pipe about on a level with the surface of the filter beds. This design of the distribution system, therefore, eliminates the use of vertical risers, which are required when the distributors are laid along the floor of the filter beds.

After the joints in the cast-iron pipe distributors have been made with jute packing and lead the pipes are to be tapped with a 2½-in. hole and threaded to receive the distributor nozzles. The specifications lay stress upon the care which must be taken to drill and tap these holes so that the nozzles when inserted shall have their vertical axes exactly plumb. The nozzles will be spaced on 15-ft. centres along the distributor pipes and will throw a circular spray. The type of nozzle to be used has not yet been selected.

Secondary Settling Tanks.—The sprinkling filter effluent will be delivered by a 30-in. concrete conduit into four secondary settling tanks, designed to intercept any solid matter which may be washed out of the sprinkling filters. These secondary tanks are circular in plan, 30 ft. in diameter, 24 ft. deep, with hopper-shaped bottoms. The inlet to each tank is in the form of a cylindrical shell of ¼-in. boiler plate, to which is connected a 15-in. spiral riveted pipe. This inlet cylinder is open at both ends and serves to collect any floating matter which may be carried down to the tank. The effluent will pass over weirs into circular channels around the tops of the tanks and will flow down stepped inclines to an open concrete-lined channel leading to the north branch of the Nashua River. The sludge from these tanks will be removed by a motor-driven centrifugal pump and discharged into the sewage entering the Imhoff tanks, in which it will settle and be further digested with the suspended matters of the sewage. By this procedure it is hoped that the offensive and slowly drying secondary tank sludge can be successfully dried.

Sludge from the Imhoff tanks and from the secondary settling tanks will be dried upon a bed of sand composed of grains having an effective size of at least 0.15 mm. and a uniformity coefficient not exceeding 10. The porous character of the underlying material made it unnecessary to install any system of underdrainage. The bed will be separated into long strips, 15 ft. wide, by concrete posts and planks, and along the centre of each strip will be laid a narrow-gauge railway track to carry cars, into which the dried sludge will be shovelled and carried away.

The works are designed for a capacity of sewage equivalent to 100 gals. per capita per day, which is approximately the amount of water consumed, the tanks providing for an estimated population of 55,000 in 1925. It is expected that the entire plant will be ready for the treatment of sewage early in 1914.

PRINCIPLES OF SHOP DESIGN.*

The laying out of machine shops must depend on the area, the shape of the ground available, and the nature of the product manufactured by a firm. The aim should always be to avoid handling materials and products more than is absolutely essential. To this end certain relations of shops to each other, and to railway sidings or canals, will have to be observed, in addition to the internal designs of the shops, the placing of heavy and light machines therein, and the systems of industrial railways and dispositions of hoisting machinery; so that the main problem includes much detail that varies with the requirements of different classes of manufacture.

With respect to the relative positions of shops as affecting the handling of work, two general cases arise. One is that of concentration in a few buildings, the other their isolation in separate buildings. In a large degree the choice between these depends on the size of a concern. The larger it is, the more desirable does the isolation of shops and of departments in shops become, partly because the necessities of supervision, partly of those of higher specialization. A small firm can carry on its machining and assembling work all under one roof, in charge of one foreman. A very large works must not only separate these departments, but must also create sub-departments in each, for light and for heavy work at least; and very often further sections must be ar-

*Condensed from The Times (London) Engineering Supplement.

ranged according to the class of machine used, as planers, drills, gear cutters, grinders, and so on. Then the question arises whether all these shall be included in one large shop covered by one roof, or be housed in separate buildings or on distinct floors, which can be decided only for each individual firm. Speaking broadly, the present tendency is towards isolation where the work done is of a sufficiently standardized and repetitive character to justify it.

But whatever arrangements are adopted, the cardinal element of economical haulage and handling must not be lost sight of. Raw materials—bars, castings, and forgings—should be taken in, and should, with the articles manufactured from them, not return on their tracks, but should progress from shop to shop, or department to department, in orderly sequence; and this idea must be uppermost when locating the positions of those departments in which preparatory work has to be done, as the casting, forging and plating departments, and the stores for iron and steel. Raw material should, as a rule, be utilized first nearest the point of debarkation. The heavy machine shops into which castings and forgings have to be taken should be located nearer to the foundry, forge shop, or boiler shop than the department in which light work has to be done.

It is well as a rule, when work is for the most part heavy, to conduct operations so far as possible on the ground level. There is, however, always a proportion, greater or less, of light work, and this can well be conducted on upper floors, or in galleries running round a shop, the latter usually having preference. In shops in which most of the work is light, as in the manufacture of small motors, brass fittings, and articles of similar bulk, floors and elevators can properly be utilized. But lack of light renders fine work difficult on dark days and runs up the bill for gas or electricity.

Instead of building in the heart of a crowded city, most new factories are now erected in the suburbs of cities, or out in the country where ground is cheap and room for extension is ample, and where healthful cottage homes can be built for the workmen.

The arrangement of shops on a ground floor only is the modern ideal in factory design, and it is one which is admirably suited for engineering works. The work being mostly of a heavy character, its manipulation is awkward on upper floors, but if it can all be dealt with on a ground floor it can be run in and out, handled with hoists and cranes, while all the trouble of lifting and lowering from upper floors is avoided. Supervision, again, is easier on one floor than on several. A manager or foreman can have more men under more effectual observation, whereas different floors require either extra foremen or divided attention. Hoisting machinery can be more efficiently installed on a ground-floor shop than in a building of several stories.

With regard to the buildings themselves, it is better and cheaper to build one-story shops than those with several floors. The walls, having no floors to carry, need not be so thick, and there is no expense for heavy joists, floor planking or concrete. More light can be admitted from the roof than from windows in walls, and a north light can be obtained with a saw-tooth roof, which avoids the direct glare of sunshine. With regard to the walls, in most engineering works they are made to fulfil other functions besides that of sustaining the roof. Details which have to be considered are the support of travellers and jib cranes, of main lines of shafting and countershafts, and sometimes of machines, such as wall planers, drills, etc., in whole or in part. Brick walls alone are not nearly so suitable for the fulfilment of these functions as are metal columns. This is one cogent reason why columns are generally preferred to brickwork, and it is all in favor of the ground-floor shop in which columns take the place of brick walls as supports, the wall often being a mere filling in of a brick course, or even sometimes of sheet iron, between the columns.

Further, the modern shop ideal is to have an unbroken width across two, three, or half a dozen bays. Each bay has its own roof, but the bays are separated only by columns, which leave clear wide spaces across the entire width that is enclosed by the outer walls. The columns, of cast iron or structural steel, are made to suit exactly the requirements of the shop, with flanges and brackets to receive the gantries of overhead cranes, the pivots of swinging cranes, bearings for shafting or countershafts, and attachments for wall machines. In the event of future shop extensions these bays can be carried out lengthwise by making more identical columns, preserving the uniformity in width and height of the shop. In a well-lighted shop built on this model there is no objection to the erection of galleries of moderate width, provided they do not interfere with the employment of suitable hoisting tackle. They would sometimes block the way of an overhead traveller, but the latter is not required in light departments. Moreover, galleries need not occupy all the length, and they may be raised higher than the crane gantries. Where space is limited the galleried shops often offer the best solution of a difficulty.

Hoisting machinery is a costly item, and one in the laying down of which the best judgment is required. There are so many systems of hoisting adopted now that it is difficult to give statements of general application. But the following considerations should have weight. In the shops themselves the choice lies between overhead tracks with hoists, overhead travellers, and walking or single-post cranes. The choice of the first two should be favored because they leave an absolutely clear way beneath. But many firms employ the walking cranes, especially in machine shops. Wall cranes will often be needed both for light loads and the local service of heavy machines. Floor trolley tracks are often used. In the yards there should be travelling steam or electric cranes to go wherever required for unloading or loading, for hauling or pushing, in the absence of a yard locomotive.

The hoisting mechanisms for light service which run along the overhead tracks may be divided into two great groups; those which are trolleys only, having eyes from which the actual hoisting machines are suspended, and those that combine the travelling and hoisting tackle in one. The first-named are mostly of the direct lift types, worked by hand, pneumatic, or hydraulic power; the second are electrical. In the hand hoists pulley blocks are suspended from trolleys pulled along by hand. In the pneumatic and hydraulic types the movement of a piston or ram in a cylinder is equal to that of the lift. In electrical hoists toothed gears, drum and wire rope are employed, driven by the motor located on the trolley. The movements of the latter may be controlled from a distance, but more commonly dependent rods with handles are employed, so that the men standing by their loads can operate the hoist from the floor. So extensive are these developments that several firms in England and America make a specialty of the fitting of overhead tracks and light hoists for them. For heavy duty overhead travelling cranes are practically universal. They are made in many styles and powers to suit all conditions, operated from above and from the floor, and as a rule now each motion is provided with its own separate motor.

Alternative to the overhead tracks are the walking or single-rail cranes, which have for a long time been favorites in the machine shops of the Manchester district and north country shops. They occupy only the room in which they happen to be engaged for the time being, and the single line of floor and overhead rails does not block the shop much. As they are slewing jib cranes, they cover an area corresponding with the entire sweep of the jib.

CONTENTS OF THIS ISSUE.

THE ENGINEER AND THE COMMUNITY.

Dr. George Fillmore Swain, in his presidential address to the American Society of Civil Engineers at Ottawa, last week, on the part for the engineer to play in the solution of some of the problems of the present day, unconsciously expresses himself as an engineer, among his fellowmen, with an astonishingly broad conception of the relationship of men of this profession to society in general. Frequently, in late years, writers have discussed the subject, and from both sides. Taking the definition of an engineer as one who, possessing a knowledge of the laws and properties of matter, designs and constructs, and, realizing the superior facilities of communication, transportation, food preservation, water purification, etc., as the works of the engineer, the question of what he owes to society is lost in that concerning how much society owes to him. On the other hand, the reason why the engineer does not receive the praise and credit which is his due, has often been attributed to the aloofness with which he holds himself from the discussion of public improvements and the administration of governmental departments and affairs.

Rear Admiral Geo. W. Melville, retired from the United States Navy, in discussing the engineer as a citizen, stated a few years ago:—

"In view of the enormously important part which the engineer plays in the life of to-day, it is incumbent upon him, more than upon most other men, to take a vital interest in the work of government, and to lend his trained ability and judgment to its perfection. I do not mean, of course, that the engineer should do routine professional work for the governments without compensation, but that in the discussion of public improvements and the administration of governmental departments he should take an active public stand to influence and guide the non-expert part of the population.

"It is notorious that enormous amounts of money have been squandered on great public works because they were undertaken in a way which every engineer knew must be inefficient and uneconomical. If all of us as engineers had a keen sense of our duty in this respect, and would properly utilize our experience and ability through the daily press, the magazines, and the reviews, by public discussion and in the daily intercourse of life, as well as by impressing the truth upon our representatives in municipal and national affairs, I believe we should accomplish an immense amount of good."

Prof. Swain's address is one from a viewpoint not frequently found in the writings of engineers, and his masterly treatment of the undesirable phenomena to be found on the increase among men to-day should receive every reader's attention.

ENGINEERING CONVENTIONS.

These are convention days among engineers. This week has such an array of professional gatherings that doubtless the old saying that engineers are content to work, leaving the talking and the management to the lawyer and the politician, will be criticized by the wayfarers in other walks of life, who find them gathered together in hall, hotel, or railway carriage.

Of world-wide interest is the Third International Roads Congress, opened on Monday in London, Eng., and continuing throughout the week. The period of continued activity in road reform that has prevailed since the second Congress, three years ago in Brussels, has seen many methods, and not a few materials, introduce themselves, and pass from the experimental to the prac-

tical stage. Further improvements in methods of road construction and maintenance will be disclosed, to the thirty-six countries of the world represented there, and the newest information now available will be dispensed from these various sources, with regard to climatic influences, heavy trafficking, dust prevention, longevity of surfacings, frequency of renewals, etc. As it stands, technical knowledge of road-building is far in advance of road administration to govern it, and it is to be hoped that the Congress in London will bear fruit in much-needed data concerning road costs.

In Toronto the Canadian Electrical Association is in convention on the 25th, 26th and 27th, and not in Fort William as had previously been announced. Arrangements for convening in the latter city were not satisfactorily arrived at, and Toronto was chosen as the place of meeting. Technical papers are being presented at the Wednesday and Thursday sessions, and the balance of the assembly is being given over to excursions and entertainment.

The American Waterworks Association, in session at Minneapolis throughout the week, is fortunate in the choice of city. No doubt the immense filtration plant, representing the latest word in water purification, will receive its share of visitors. Authoritative papers are being read on such subjects as water purification, fire protection, ground water, rate-making, franchises and watersheds.

The American Society for the Promotion of Engineering Education holds its annual meeting this week also, and has likewise chosen Minneapolis as its city. The care and attention which this society is devoting to engineering training merits the approval of all associations in general and of individual engineers.

The American Institute of Electrical Engineers are meeting in Cooperstown, N.Y. It is their thirtieth annual convention. Some twenty papers are being presented, and many Canadian members of the Institute are in attendance.

The American Society for Testing Materials is in convention, June 24th to 28th, at Atlantic City, while the American Institute of Chemical Engineers hold their semi-annual meeting at Boston, Mass., June 25th to 28th.

PUBLICITY IN CALLING FOR TENDERS.

Unless the proposed extension is for the most part a duplication of a previous installation, manufacturers of engineers' and contractors' supplies usually expect reasonably wide publicity in the matter of requirements, being constantly on the lookout for the solicitation for tenders. In the case of a town or city, it is the general rule to purchase supplies by tender, the transaction being of such great interest to ratepayers, and not to a limited few. In some corporations the rule is rigid. Much valuable information is to be gained in dealing with the proposal submitted by tenderers, whatever the requirement may be. It is of value not only to the purchaser, but to other municipalities, and it is strange that the rule is not followed without exception.

Instances frequently come to light, however, where discrimination is practised to excess, and where forms are sent to a very small and promiscuously chosen percentage of those well prepared to submit competitive quotations on reliable supplies. Recently *The Canadian Engineer* was asked by a pipe manufacturer why a certain call for pipe and valve tenders had not appeared in its columns. Upon investigation it was found that the want, although of a city, was not advertised in any paper. Apparently it has long been the custom of the city authorities to send notice of the material required to several manufacturers only, although the city engineer is strongly in favor of widespread publicity for the benefit of other supply houses. In this case the award was made to a local firm before knowledge of the existence of the proposed extension requirements was made known to others.

Presumably it is not the desire of municipal engineers to entertain methods so unproductive and so risky. The value to them of a thorough knowledge of what firms can do in the matter of quality and prices is significant, and civic officials are not up-to-date who do not recognize the value of the competitive tendering that is ensured by advertising their calls for tenders in the technical press.

EDITORIAL COMMENT.

July 15th, 16th and 17th are the dates of the annual Convention of the Union of Canadian Municipalities in Saskatoon, Saskatchewan. Questions bearing upon public utilities, town planning, garbage incineration, water purification and the like will be discussed.

* * * *

The Fourth Annual Convention of the Pacific Highway Association will be held in Vancouver, August 11th, 12th and 13th. This association has set itself about to secure the construction of a first-class trunk road along the Pacific slope, and, with the co-operation of the Governments of both countries, and the communities along the slope, an international roadway of great service should result. Previous annual conventions have been: 1910, Seattle; 1911, Portland; 1912, San Francisco.

* * * *

One of the first duties of the new city engineer of Ottawa, which position was assumed on the 20th inst. by Mr. Arch. Currie, C.E., is an investigation into the city water supply. It is well known that it is a difficult problem, and that the office of city engineer is, therefore, not devoid of troubles of its own. The waterworks staff has applied on two recent occasions for separation from the board of works staff. The Board of Control reported unfavorably concerning the division, and it is understood that the question is now awaiting solution by the new city engineer.

* * * *

The beautification of cities is receiving splendid attention in Ontario this season. *The Canadian Engineer* in last issue announced the proposed expenditure of $7,000,000 in a forty-two mile system of boulevards to surround the city of Toronto, the work being in charge of the Parks and Exhibition Committee, and being an entirely separate enterprise from the Harbor Commission's waterfront development work. It has just been announced that Section A of the system, extending from the lake to Bloor Street along the eastern bank of the Humber River will be gone ahead with this summer, $25,000 having been appropriated for this purpose. The Government has just announced a similar scheme to embrace Ottawa and Hull. A commission is to be appointed to prepare plans for the systematic development and beautification of the two cities with regard to parks, boulevards, public buildings, etc. The traffic and transportation problems will doubtless be included in this work, and the co-operation of the transportation companies is to be expected. The mayors of the two cities are to be members of the commission. Half the cost of the scheme of planning is to be borne by the government and the other half by the two cities.

TORONTO WATERWORKS EXTENSIONS

COMMISSIONER HARRIS EXPECTED TO MAKE THOROUGH REPORT NEXT MONTH — TWO MECHANICAL FILTRATION PLANTS — SCARBORO HEIGHTS SCHEME ABANDONED

Commissioner of Works R. C. Harris, of Toronto, is now gathering the final data for his report to the city's Board of Control regarding the proposed extensions to Toronto's waterworks system. The Commissioner's report will likely be presented to the Board next month, and tenders will be called for, very soon thereafter, for a new filtration plant.

The citizens of Toronto voted $6,000,000 on January 1st, 1913, for waterworks extensions. Although six months have passed since then, practically none of this money has been spent, and no official announcement has been made at any time as to why the Works Department of the city was not going ahead with the extensions. At a cost of about $26,000, a detailed report had been obtained by the city in 1912 from a board of four engineers, who were appointed, prior to the present administration of the Works Department, to advise the city of the best plan of making the necessary extensions to the available pure water supply. The board, consisting of J. G. Sing, chairman; Willis Chipman, secretary; T. Aird Murray, and Isham Randolph, reported in favor of a gravity supply system from Scarboro Heights, the water to be pumped from the bottom of the lake off Scarboro to the Heights, from which place it was to flow through from nine to twelve miles of pipe to the city, after being filtered at Scarboro.

This report was generally accepted, and when the citizens voted on the $6,000,000 by-law, it was popularly understood that the money was to be used in carrying out the board's report. Just about that time *The Canadian Engineer* pointed out a number of serious defects in the report which made the Scarboro Heights scheme seem entirely impracticable. *The Canadian Engineer* called attention to the greatly underestimated cost of the Scarboro Heights undertaking; to the possibility of getting the same result at a much cheaper cost by putting the plant at the Island, and using direct pumping instead of the gravity system; to the lack of flexibility of the gravity system; to the great waste of power in pumping water up to Scarboro Heights, only to expend the acquired head in friction when the water ran through miles of pipe to reach the city; and several other details that caused much comment in the public press at the time. The comments of *The Canadian Engineer* were actively replied to by three of the Commissioners, Mr. Murray, however, admitting the errors of the report in letters to the Mayor.

The other three members of the Commission met the City Council and endeavored to explain away the defects in the report that had been pointed out from time to time. The Commissioner of Works, however, laid the report of the experts to one side and decided to prepare a report of his own for the Board of Control, basing his report upon the experience and research work of the city's own engineering staff.

Consequently, the extension of the waterworks system was held up until the Commissioner's staff had secured such information that they were prepared to report with confidence to the Board of Control, advocating a scheme of extension far more practical than the Scarboro Heights scheme.

It is understood that after six months' careful survey of the situation, the Department of Works will in all probability advise the City Council to install a rapid sand filtration plant at the Island and to distribute the water to the city by direct pumping.

The report to be made by the Commissioner of Works early next month will be extremely thorough. The Commissioner has investigated every phase of the problem, and his report will undoubtedly overlook nothing that has any bearing upon the situation. The history of Toronto's existing slow sand filtration plant will be related, the difficulties that have been experienced with it will be explained, and the reasons clearly given as to why Toronto is now turning to rapid sand filtration.

A report will be given of the various types of filtration plants visited by the Commissioner of Works and other officials of the city during the past year, and recommendations will probably be made that the Board of Control call immediately for tenders for a rapid sand filtration plant of sixty million Imperial gallons capacity. Each tenderer will be required to file plans and specifications of his plant, together with his tender. Each tenderer will be required to guarantee the efficiency of his plant; the daily capacity, and the maximum cost of operation, chemicals, etc. The award will then be made to the plant which will cost the city the least money compared with the efficiency guaranteed. In computing this, the "cost" will include not only the first cost of the plant, but the capitalized cost of operation, chemicals, etc.

The water from this new plant will be brought across Toronto Bay through the existing tunnel, which has a daily capacity of from one hundred and ten to one hundred and twenty million gallons. As the existing slow sand plant has a capacity of only forty million gallons a day when not over-loaded, the tunnel will readily handle the one hundred million gallons per day total output of the two plants.

The city's electrical pumping capacity at the present time is fifty-four million gallons daily. The steam pumping capacity is fifty million gallons. A sixteen million gallon pumping unit is now being built for the city by the De Laval Steam Turbine Company, of New Jersey, and in all probability another steam unit will be installed at a later date. The steam pumping capacity will likely in time be brought up to the one hundred million gallons per day that the filtration plants will handle.

Under this scheme, however, Toronto would still obtain all of its water supply through the tunnel under the Bay. Should any accident occur to this tunnel, the situation would be serious; and, with this in view, the Commissioner will likely recommend in the near future that a filtration plant, of probably about sixty million gallons daily capacity, be located in East Toronto. It will not be located at Scarboro Heights, however. The water from the plant will likely be delivered to the East End by direct pumping. This plant will pump directly from the lake and will provide Toronto with a water supply independent of the tunnel.

Although Mr. Allen Hazen and his partners are still urging the city to stick to slow sand filtration, it is not likely, for a number of reasons, that the Commissioner

of Works will consider any tenders for plants that are based on slow sand filtration, but will consider only the gravity and pressure systems of mechanical filtration, and the drifting sand type of filter.

There are numerous plants on this continent of the first two types mentioned, but only one plant of the last type, and that is an experimental plant which is now in operation at West Toronto. It is a half million per day plant, and is filtering to waste. It was built entirely at the expense of the company that controls the patents on this type of filter, and was built to convince the Commissioner of Works that when calling for tenders he would be justified in giving consideration to a tender on this type of filter. The experimental plant has been in operation for a little over a month, and the results have been carefully watched by officials from the City Hall, and a tender on the drifting sand type of filtration will likely receive consideration by the officials, along with the tenders on the other two older and more widely recognized types.

As the western part of the city increases in population, another filtration plant similar to the one proposed for East Toronto will likely be installed at West Toronto, so as to make the city entirely independent of any one source of supply.

THE ENGINEER AND THE SOCIAL PROBLEMS

THE PROFESSION AS A PART OF THE SOCIAL ORGANISM — PRESENT DAY CONDITIONS AND TENDENCIES — PRESIDENTIAL ADDRESS, AMERICAN SOCIETY OF CIVIL ENGINEERS' CONVENTION, OTTAWA, ONTARIO, JUNE 17th TO 20th

By DR. GEORGE FILLMORE SWAIN, Pres. Am. Soc. C.E.

NOTE.—This article, a continuation of which will appear in next week's issue, is abstracted from Dr. Swain's address. Readers desiring copies of his paper, complete with references, footnotes, etc., may procure the same by applying to *The Canadian Engineer* for them. The paper isbeing prepared in pamphlet form and copies will be sent upon request as long as the supply lasts.—ED.

IN asking your attention this afternoon to the remarks which I shall offer for your consideration, I cannot forbear expressing to you, once again, my appreciation of the honor which you have done me in electing me to the position in which I find myself. It is a distinction which I shall always value above any other, and it involves a responsibility to the profession of which I am deeply sensible. This feeling, together with my conviction of the importance of our profession as a part of the social organism, has guided my choice of a subject for this address.

As we gather here, interested in widely divergent branches of engineering science, it has seemed to me that I could most profitably occupy the time by asking your attention to some matters in which we all should be equally interested. I have, therefore, chosen for my subject a consideration of some Tendencies and Problems of the Present Day, and the part which the engineer should play in their solution.

We are living in a most remarkable age, an age different from any that has preceded it in the history of the world, and and one in which changes are taking place with marvelous rapidity. As a profession, we are largely responsible for the present conditions, and as such we should do our part in solving such problems as exist, and in helping to direct aright the tendencies of the day. We have a duty to ourselves, to our profession, to society, and to our successors, and we must perform it.

We have been often reminded of the fact that in one sense engineering is the oldest of the professions, since engineering constructions of some form are necessary even in the rudest communities. But in another, and perhaps a truer sense, it is the youngest of the professions. The priesthood is doubtless the oldest distinct profession recognized as such, for the most uncivilized tribes had priests to mediate between themselves and their crude deities. The priests were also law-givers, practiced the healing art (such as it was), and, as civilization progressed, were also the builders. Bridges and temples were built by them, and the most stately buildings were those devoted to ecclesiastical uses. In course of time, the lawgiver, the physician, the architect, became distinct, and then for a time the engineer was either an architect or a priest. It is fair to say that engineering is the last profession to be differentiated into a class by itself, and that its beginning dates from about the 17th century, and later received its great impetus from the series of inventions which were made toward the end of the 18th century; the spinning jenny, the loom, the puddling process, the steam engine, and the steam locomotive. Since that time, the profession has grown by leaps and bounds, has become separated into a dozen branches, and has probably become, directly or indirectly, the chief occupation of mankind. If this age may be designated as predominantly that of any profession, it is certainly the age of the engineer, or applied scientist. He furnishes us with thousands of comforts, necessities, and luxuries, of which previous generations never dreamed, and which they would have laughed at as impossible. By supplying the fundamental material elements of modern civilization—transportation, the transmission and dissemination of intelligence (by telegraph, telephone, and printing press) machinery, prime movers and the working of metals—the applied scientist becomes the minister to the other and older professions, furnishing tools for the surgeon and dentist, and chemical products for the physician; while engineering projects and problems probably supply as large a field as any for the employment of lawyers. The priest—originally lawgiver, physician and builder—now stands alone, concerned only with the moral law and its application, and with our relation to the Infinite.

Civilization, as we know it to-day, then, seems to me to be due mainly to the engineer, or applied scientist, using the term in its widest sense. Of course, a great ethical advance has also been made, of which any student of history must be fully conscious. But when we consider that moral principles were known and recognized by the ancients, in as perfect a form as that in which they can be stated to-day, without producing much of any widespread ethical progress or any advance in civilization for many centuries, we must, I think, conclude that it is the dissemination of intelligence, the facilities for transportation, the development of machinery, which have made the whole world kin, and thus have been

the chief elements in promoting the universal brotherhood of man and the practical recognition of human rights, and so have been the main agents in the progress of civilization. This, somewhat differently expressed, is, as I understand it, the position taken by Buckle, often misunderstood by those who assume him to assert that no ethical progress has been made. However this may be, few will deny that the work of the engineer, if not the cause, has been a necessary condition of progress.

This progress, both material and ethical, has been widespread and astonishing in degree. In material things, not only necessities, but comforts and luxuries of which our forefathers would never have dreamed, are now within the reach of every man who is sober and industrious. Wages have risen, not only in absolute amount, but in purchasing power. The poor can now receive medical advice, medicines, and many other things free, where our predecessors could not have obtained the same things at all. Simple foods in great variety, and clothing of good quality, can be obtained at reasonable prices, and in every respect the poor man to-day is better provided for than his predecessors were. Ethically, too, he is far better off. The best books are available, if he wants them, at ridiculously low prices, free public schools are provided for his children, and all sorts of free industrial and vocational instruction is available for him in his leisure hours if he desires to use them. His hours of labor have been shortened, his civil rights have been generally recognized, he is treated as the equal of any man before the law, and his right to a fair chance in life—to opportunities commensurate with his ability to make use of them—is generally admitted in theory if not yet entirely in fact. With free public and trade schools, with conditions which allow a common laborer in a steel mill at 15 years of age to become the head of the greatest industrial organization in the world at 50, certainly it cannot be said that men do not have opportunity in this country.

But, continued progress and the interest of the social organism as a whole, require that individual initiative and ability shall be encouraged to the utmost and allowed to enjoy the reasonable fruits of its exercises; that property shall be protected; that taxation shall be equitable and uniform; that leaders shall be chosen from those most enlightened, capable, honest and judicious; that those who are only fitted for manual labor shall not acquire a distaste for it or look down upon it as inferior in dignity to other occupations; and that waste and extravagance shall be reduced to a minimum. There should be a recognition of the facts that wealth must be unequally divided, since men are unequal in ability and in character; that the prosperity of one depends upon the prosperity of all; that each man must feel secure in the enjoyment of all that he can legitimately win; that wealth, position, and luxury, do not in themselves bring happiness; and that the selfish desires of the individual must be subordinated to the interests of society as a whole if progress and not retrogression is to ensue. A state of equality of condition, as has been well remarked, would mean equality, not of wealth, but of wretchedness.

The political and social evolution in the past has, up to a comparatively recent period, not involved any diminution of the incentive to individual effort, nor to any great extent the attempt to deprive the individual of the fruits of his industry and ability. Of late years, however, with growing political power in the hands of the less intelligent classes, symptoms of a change have shown themselves. The spectacle of isolated instances of great wealth acquired unfairly or too rapidly, and of rewards out of proportion to service, instead of being looked upon as necessary phenomena, seeing that men are human, and that no human affairs can ever be perfect, has lead to a widespread spirit of envy and discontent, and sometimes to a desire to deprive men of the results of their honest toil.

It is to some unfavorable phenomena incident to this movement that I wish to call your attention, believing that if they continue, disaster may result, in which case, as always, the suffering will mainly come upon those least able to bear it.

Equality Among Men.—What I conceive to be the true democratic ideal is this: that all men are equal before the law—so that neither differences in wealth, race, social position nor talent shall confer any advantage or impose any disadvantage in the impartial administration of justice; that while ability may be admired, every man who is honest, industrious, sober, and faithful, and who does his work in the world as well as he can and with due regard to the rights of others, is deserving of equal respect and regard, whether he occupy the humblest or the most exalted position; that success depends upon the spirit with which one's natural endowments are utilized and the degree to which they are developed, and not upon those endowments themselves, so that the humblest laborer on the street may be making as great a success of his life as the most gifted; that there should be kindliness and a spirit of brotherhood between all men and neither envy of those more capable, who receive greater rewards, nor contempt of those less gifted, who do the menial work of the world; and that neither race, poverty, nor inferior social position should prevent the possibility that a man, by hard work, integrity, and conscientiousness should be able to reach, by some available ladder, a position commensurate with his abilities. A man should be judged by what he is, not by what he has, whether he is black or white, or who his grandmother was. He should have the opportunity to get such education as best fits his natural qualifications. Rich and poor should be judged by the same standard—inherent worth. But though respect should be equal, rewards should not be, but should be in proportion to the value of the service, and governed by the law of supply and demand; nor are great rewards necessary for happiness.

Unfortunately, a democratic government, especially with universal suffrage, instead of tending to the realization of this ideal, tends in some respects directly away from it, and leads not seldom to the grossest perversions of it. The equality of man, which the framers of the Declaration of Independence held to be self-evident, instead of being interpreted as above, is held to mean that men are inherently equal in all respects.

It is self-evident that instead of being equal, men are very unequal. There is perhaps more difference between the most intelligent and the least intelligent voter than there is between the latter and an intelligent animal. It is held that all, being equal, should have equal opportunity. But why should there be equality of opportunity for unequal individuals? Inequality of opportunity for unequal men is a nearer approach to true equality than equal opportunity for unequal men. Why, for instance, should all men have opportunity for a college education, when only a few can profit by it, and the great majority should work with their hands, not with their heads? Not every man who is able to pass successfully through a college course is able to use it when he has finished, and many a good mechanic has by its means been spoiled to make a poor and discontented clerk or lawyer.

One of the conditions of individual progress is the willingness to recognize and admire superiority, and without envy to rejoice in its success. The idea of the equality of man limits this recognition, and so hampers individual progress, and therefore collective progress. In college, there is

little in class associations to stimulate a man to excel. If he does, he is termed a "grind" and is looked down upon. If all men are equal, he has no right to exhibit any superiority to his fellows. The same is true among the so-called laboring classes. No man must do any more work, or do it any better than another. Individual excellence and initiative are discouraged. Indeed, individual freedom is not seldom infringed upon, and a man is not allowed, at times, to work at wages satisfactory to himself, when he desires to do so—a strange result of freedom, and in reality as great an outrage as any that can be quoted from the medieval annals of despotism. With growing discontent, many minds turn to socialism, that impracticable Utopia which, as President Butler has well said, "would wreck the world's efficiency for the purpose of redistributing the world's discontent."

The idea of the equality of man, instead of allowing the best men to govern and fitting the man to the proper vocation, leads to the placing of unfit men in power, the control of large masses of men by demagogues, the judging of men by the number of votes they control; and thus it leads to the withdrawal of many of the best men from active participation in public affairs, because they see how little influence they can exert, and that the only reward of one who unselfishly serves the public is likely to be criticism and contumely. It also discourages loyal and faithful service, and makes difficult the maintenance of proper relations between employer and employees.

What the ultimate result will be, cannot be foretold. The political doctrine of the equality of man is still a trial. Yet, as regards the United States, where that doctrine has its present expression, Lincoln long ago observed that if it fails, it will not be on account of interference from without, but it will be by suicide. It behoves us, therefore, if we can, to see to it that our institutions shall not fail by suicide.

Nevertheless, it is a somewhat striking fact, that several of the most philosophical and learned historians have distrusted the ultimate success of our institutions. Froude, Macaulay and Lecky all express the gravest doubt of the permanence of our form of government.

These predictions will, we hope, prove erroneous. We must make them so if we can. Nevertheless, the more we reflect, the more I think we shall realize that out of the false theory of the equality of man, have sprung many real dangers. A spirit of unhealthy discontent has been aroused, and the people, who are sovereign, endeavor by various kinds of legislation, to realize in fact the untruth of equality. They make the common mistake of assuming that legislation is a sovereign remedy for all ills. Not knowing how to proceed, they become the prey of every selfish demagogue who, while stirring them up to exaggerate their troubles, and professing his ability to remedy them, is simply seeking his own ends. These men know that a large part of the voters to whom they must appeal are ignorant, easily swayed by claptrap and deceived by hypocrisy, "incapable of disentangling a difficult question, judging distant and obscure consequences, realizing conditions of thought and life widely different from their own, estimating political measures according to their true proportionate value, and weighing nicely balanced arguments in a judicial spirit." The demagogue therefore appeals to class interests and class animosities, and does his utmost to foment a spirit of discontent, even though every condition justifies the opposite, gaining his reward by newspaper headlines, notoriety, public office, or not seldom, wealth secured at the expense of the public that he deceives. The spirit of servility and sycophancy which in former times led men to grovel in the dust at the feet of kings and princes, is still with us, unchanged in form. Only its object is different, and its adulation is now directed to the sovereign voter—the more ignorant, the more easy to flatter and deceive. Knowing human nature, may we not doubt the man who claims to act for the good of the people; and trust him rather who frankly admits that his actions are governed by his selfish interests, but who has learned that these can only be served by promoting the best interests of all.

Some of the remedies for these dangers, it seems to me, are obvious. In the first place, we should realize that the statement that all men are created equal, properly interpreted, simply means that they are equal before the law, that all men should be treated with justice, should have fair opportunities, and that each should be secured in his right to the products of his own labor, and to his own liberty, so far as his acts do not injure others. Aside from this, instead of considering men equal, we should recognize and encourage inequality, for it is easily to be seen that the progress of society depends upon it. Equality of condition means pauperism or savagery; the inequality of man means the division of labor, progress, civilization.

In the second place, we should encourage the recognition and admiration of superiority.

In the third place, we should preach the gospel of content instead of discontent. There are two kinds of discontent; one praiseworthy; one ignoble. The former springs from a laudable ambition and a desire to perfect one's self, so far as natural endowment will permit. The other springs from envy and the desire to reap the rewards of the industry of others. The former kind of discontent is to be encouraged; every man should be given an opportunity to develop himself and to be confirmed in the possession of the prizes which he may gain. But the discontent which springs from envy, which leads men to depend upon government help, instead of self help, which sanctions forms of unjust taxation which may be nothing less than legalized robbery, should in every possible way be repressed. The attention of men, instead of being concentrated on what they want, should be more directed to a realization of what they have. In contrast with the conditions which existed one or two centuries ago, even the conditions of the poorest classes at the present time are immensely improved. Yet, with all the reduction of working hours that has taken place in the last 50 years, and the other improvements in condition, I doubt if there is any more real happiness and content among the poorer classes. Nor have I any doubt that the excessive talk about bettering the condition of the working classes, blinds them to the opportunities for their own thrift and industry.

Unfortunately, it is a vain hope that there will ever be an absence, or even a dearth, of demagogues to stir up this spirit of unworthy discontent, but we should do all in our power to counteract it. Unfortunately, also, much of it is due to the unwise use of wealth by those who possess it, who think that money can buy everything, and is the end and aim of existence, and who, instead of being governed by a feeling of the brotherhood of man, and the spirit of respect for true worth even in the humblest occupations, assume an attitude of superiority, or even of insolence, towards those less fortunate than themselves.

It is vain to hope that we can ever reach a point where there will be no poverty. This would realize what Dr. Johnson termed the triumph of hope over experience. It would mean a radical change in human nature. As long as there are masses of men who are shiftless, lazy, incompetent, and vicious, whom nobody would willingly employ, poverty will exist. Still, every effort should be made to relieve it where it is undeserved. It will be well, however, to bear in mind that suffering is a remedy, and that unwise philan-

thropy may do harm instead of good. If men will learn in no other way the lessons of life, they must learn them by suffering, which is Nature's cure. Of course, it is often hard to distinguish deserved from undeserved suffering. The latter may be wisely relieved; the former generally not. Surely an all wise Creator would not have filled the world so full of it except for some good purpose, and that purpose cannot be to afford to others the opportunity for relieving it, for much of it cannot be relieved.

The Tendency to Disregard Authority.—Out of the tendency to look upon all men as equal, spring some other tendencies to which I will refer. One of them is to disregard authority, and to consider that one man's opinion is as good as that of any other. We see this tendency about us every day; it leads to intellectual arrogance, dognatism and lawlessness.

Every man has presented to him, almost daily, questions which he is not competent to decide for himself, either because he has not had the necessary time, training or experience, or because he is incapable of judging.

In these days when literature is so superabundant, it is most important to choose our advisors wisely, to know whom to trust, to discern wisdom, to select the proper books to read, to choose the best authorities to whom we shall listen, and, when we have so chosen, to consider attentively the message they bring, and to distinguish advice that springs from self-interest from that which is disinterested. There is a great temptation to form hasty or immature judgments on slight authority, and the habit, once formed, may be difficult to eradicate.

The disregard of authority is peculiarly observable in the younger generation. It is not confined to the uneducated, but is even more observable in many whose self-esteem has been increased by a course in college. Finding that men disagree on almost every subject, and that even those in positions of authority do not hold the same opinion, it is easy to conclude that one man's opinion is as good as another's. Let us examine this matter further.

The subjects of study may be broadly divided into three classes: 1st, the relations of abstract ideas, that is, mathematics and logic; 2nd, natural science; 3rd, the so-called humanities.

With regard to subjects in the first class, no observation or experience is necessary, and there will be no differences of opinion. They are not, properly speaking, matters of opinion at all. There can be no discussion as to whether two and two make four, or as to whether the three angles of a triangle amount together to two right angles.

With regard to natural science, conclusions depend to some extent upon observation, experiment, and experience Hypotheses may be formulated, experiments made, conclusions deduced therefrom, and differing conclusions may be arrived at by different persons. In this class then, there may reasonably be divergencies of opinion. These subjects are, therefore, less definite, more hypothetical, more uncertain. than those in the first class.

Under the third class are comprised what are called mental and moral philosophy, politics, government, history, language, etc. This class of subjects is even more uncertain and less definite than the second. Experiments are less applicable and less likely to lead to definite results, the data are more shifting and variable, experience is of great value, and extreme differences of opinion will often occur.

The thoughtful man will recognize these differences between the various subjects of investigation. He will form his conclusions upon subjects in the first class with definiteness and certainty, and will be justified in feeling confident of their correctness. He will recognize the greater indefiniteness of subjects in the second class, and if he forms definite opinions, he will hold them in a sort of tentative manner, realizing that the next experiment or discovery, or greater experience, may show them to be incorrect. He will realize the still greater indefiniteness of subjects in the third class, and while he may well form definite opinions regarding these also, he will hold them with still greater modesty, realizing that in almost every question of this character there is much to be said on the other side, and that he may be entirely wrong. Only the man who has studied the subjects in all three of these classes will realize fully the different degrees of certainty attaching to each. Such a man will be much more modest and safe in his conclusions than a man who has studied only one class of subjects. It may further be remarked that a man who has studied only the third class of subjects, will be likely to be more dogmatic and less safe than a man who has studied the first or the second, or both, because not being familiar with subjects in which a great degree of certainty, or even absolute certainty, is attainable, he may assume that such degree of certainty is attainable in the subjects of the third class; whereas, a man who has studied mathematics or science, and is accustomed to definiteness, will, when he is confronted with problems of politics, government, or ethics, be at once struck with the great difference in reliability of the data, the impossibility in many cases of making crucial experiments, and the fluctuating conditions involved. For this reason, it is not uncommon that scientists, mathematicians, or engineers hold and express opinions regarding politics, economics or ethics, with much less dogmatism than less well-informed men who have devoted their attention more strictly to these last-named subjects.

(To be continued.)

TRADE DISPUTES DURING MAY.

The record of trade disputes maintained by the Department of Labor shows that, as is usual at this season, the majority of the disputes occurred pending the adjustment of new wage schedules. These were nearly all of short duration. The mining industry on Vancouver Island was seriously interfered with, more than 3,000 men being out during the whole month through the continuance of the dispute at Ladysmith and Cumberland mines, and the closing down of the mines in the Nanaimo District. A great number of the disputes of the month occurred among workers in the metal trades. The disputes of May affected upwards of 11,500 employees and accounted for the loss of more than 150,000 working days. Disputes affecting various classes of municipal employees in Vancouver and affecting also the boot and shoe workers in a number of the factories in Quebec were satisfactorily adjusted during the month through the instrumentality of boards under the Industrial Disputes Investigation Act. The Department of Labor also assisted in the adjustment of disputes affecting the employees of the Hydro-Electric Commission in Toronto, and affecting also the longshoremen in Montreal and St. John, N.B. In the latter case a board has been established under the Industrial Disputes Investigation Act.

During April, 1913, the exports of Canada to the United States amounted in value to \$8,763,013, which is \$497,334 less than those of April, 1912. Her imports from the United States for the month were \$37,416,217, exceeding corresponding figures of last year by \$6,416,998.

CONVENTION OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS AT OTTAWA.

The American Society of Civil Engineers held its 45th annual convention in Ottawa at the Chateau Laurier, June 17 to 20th. The convention was held under the auspices of the Ottawa members of the American and Canadian Societies of Civil Engineers. A detailed programme of the occasion was given in May 29th issue of *The Canadian Engineer*, and it is timely to state here that the proceedings of the convention were carried out in a most exemplary manner. The meeting was largely of a social nature, which necessitated more than ordinary care and attention, and the resulting comments pertaining to the proceedings point decidedly to most admirable management.

It is 32 years since the American Society of Civil Engineers held its previous convention on Canadian soil. During the years which have elapsed since, the engineering profession in both the United States and Canada has undergone a very marked development, and while we cannot give our readers much information concerning the convention of 1881, which was held in the city of Montreal, we feel quite sure that the convention held last week in Ottawa eclipsed all conventions which the society has held up to date.

The number of delegates registered totalled something like 385, including the ladies. The convention opened on the afternoon of the 17th with a reception to the visitors, the reception duties, in the absence from the city of the Premier, falling upon the Hon. Martin Burrell, Minister of Agriculture. This event took place in the Chateau Laurier. In the afternoon of the same day, the president and officers of the American Society of Civil Engineers held an informal reception in the ballroom of the Chateau, followed by a dance.

Wednesday morning at 10 o'clock the convention was called to order at a business session and the president's address, which was undoubtedly the outstanding feature of the convention, was delivered. Prof. Swain presented an address that for thought, logical sequence, reasoning power and rhetoric, will stand unique for a long time to come. It was a classic, and during the days of the convention following the presentation of the address, it was a constant topic of conversation everywhere among the delegates. A part of this address is published in another portion of this issue.

Following the business meeting a luncheon was tendered to the visiting members by the Ottawa branch of the Canadian Society of Civil Engineers in the main dining-room of the Chateau Laurier, Mr. R. F. Uniacke, of Ottawa, occupying the chair. At his right sat Prof. Swain and on his left Sir Wilfrid Laurier. There were but two toasts, one to the King and another to the President of United States. The toast to the King was responded to by Sir Wilfrid Laurier and that to the President of United States was responded to jointly by Prof. Swain, president of the American Society of Civil Engineers, and Consul-General Foster, of Ottawa.

A Few of Those in Attendance at the Ottawa Convention.

The members and ladies then proceeded to the home of Thomas C. Keefer, C.M.G., who is a past president of the American Society of Civil Engineers, at the Manor House, Rockcliffe Park. This was a most delightful occasion. The day was perfect and it permitted the engineers of Canada and the United States to mingle in a most congenial manner.

The evening of that day was given over to three or four short illustrated talks in the ballroom of the Chateau Laurier. Mr. David A. Molitor, C.E., consulting engineer of the Toronto Harbor Commission, gave a very clear and lucid description of the Toronto Harbor Commission's work, and showed by means of a large-sized chart what that commission had set out to accomplish toward the improvement of the Toronto harbor. Mr. C. R. Coutlee, of Ottawa, gave a very interesting talk on the railway situation, while Mr. J. B. Challies, superintendent, Water Power Branch, Department

of the Interior, and Mr. R. F. Uniacke, chief engineer of the Transcontinental Railway, also delivered addresses, both illustrated by lantern slides.

Thursday was spent in visiting points of local interest. In the afternoon the delegates and the lady guests were treated to a three-hours' tour around the city, terminating at the residence of Mr. Collingwood Schreiber, C.M.G., consulting engineer to the Canadian Government, where the members and their ladies were entertained at afternoon tea.

On Thursday evening a reception was tendered by the Ottawa members of the Canadian Society of Civil Engineers to the members of the American Society of Civil Engineers and ladies attending the convention.

Special reference should be made to the work done by the combined committees of the Ottawa members of the American Society and the Canadian Society of Civil Engineers in arranging the details for the entertainment of the visitors while in Ottawa. It was no easy task which these men undertook and that they did their work to a nicety was evidenced by the expressions of appreciation on the part of the visitors. This committee did its work with a thoroughness that was noticeable to all present, and we are glad to pay tribute to them in this way. The committee consisted of the following: Lieut.-Col. W. P. Anderson, C.M.G.; A. W. Campbell, A.M. Can. Soc. C.E.; W. A. Bowden, B.A.Sc., M. Can. Soc. C.E.; C. R. Coutlee, M. Am. Soc. C.E., M. Can. Soc. C.E.; S. J. Chapleau, M. Am. Soc. C.E., M. Can. Soc. C.E.; J. B. Challies, A. M. Can. Soc. C.E.; K. M. Cameron, A. M. Am. Soc C.E., A. M. Can. Soc. C.E.; A. R. Dufresne, M. Am. Soc. C.E., M. Can. Soc. C.E.; A. A. Dion, M. Can. Soc. C.E.; Sir Sanford Fleming, M. Am. Soc. C.E., M. Can. Soc. C.E.; Gordon Grant, M. Can. Soc. C.E.; Thos. C. Keefer, C.M.G., Past President Am. Soc. C.E., Past President Can. Soc. C.E.; C. H. Keefer, M. Am. Soc. C.E., M. Can. Soc. C.E.; T. C. Keefer, Jr., A. M. Can. Soc. C.E.; Major R. W. Leonard, M. Can. Soc. C.E.; A. St. Laurent, M. Can. Soc. C.E.; E. D. Lafleur, M. Can. Soc. C.E.; A. Langlois, A. M. Am. Soc. C.E., M. Can. Soc. C.E.; A. B. Lambe, A. M. Can. Soc. C.E.; Lieut.-Col. G. S. Maunsell, A. M. Can. Soc. C.E.; G. A. Mountain, M. Can. Soc. C.E.; D. W. McLachlan, A. M. Am. Soc. C.E., A. M. Can. Soc. C.E.; J. Murphy, A. M. Can. Soc. C.E.; J. B. McRae, M. Am. Soc. C.E., M. Can. Soc. C.E.; E. H. Pense, A. M. Am. Soc. C.E., A. M. Can. Soc. C.E.; Collingwood Schreiber, C.M.G., M. Can. Soc. C.E.; W. J. Stewart, M. Can. Soc. C.E.S; J. M. Somerville, J. Taylor, A. M. Am. Soc. C.E., A. M. Can. Soc. C.E.; R. F. Uniacke, M. Can. Soc. C.E.; G. W. Volckman, M. Am. Soc. C.E., M. Can. Soc. C.E.; James White, M. Can. Soc. C.E.

The following members of the Canadian Society of Civil Engineers were among those who registered: Peter Charton, Montreal; T. C. Keefer, Ottawa; Chas. H. Keefer, Ottawa; A. W. Robinson, Montreal; Wm. McNab, Montreal; G. H. Duggan, Montreal; D. W. McLachlan, Ottawa; J. A. Jamieson, Montreal; David Molitor, Toronto; A. B. Lambe, Ottawa; F. X. T. Berlinguet, Three Rivers; Phelps Johnson, Montreal; A. M. Bouillon, Quebec; H. R. Safford, Montreal; J. H. O'Brien, Montreal; Henry Holgate, Montreal; E. Jodoin, Montreal; A. Coussineau, Ottawa; Paul A. Bique, Montreal; G. W. Volckman, Ottawa; J. A. V. Beaudry, Montreal; Col. W. P. Anderson, C.M.G., Ottawa; C. N. Monsarrat, Montreal; W. H. Breithaupt, Montreal; G. H. Bryson, Brockville; J. W. Doty, Montreal; E. H. Pense, Ottawa; F. R. Redpath, Montreal; W. O. Houston, St. Thomas; S. Bray, Ottawa; G. R. Heckle, Montreal; R. F. Uniacke, Ottawa; H. M. Davy, Ottawa; A. S. Going, Montreal; A. T. Tomlinson, Montreal; Gordon Grant, Ottawa; A. J. McCool, Ottawa; J. A. Robert, Ottawa; E. O. Sullivan, Montreal; A. W. Sullivan, Valleyfield, Que.; E. J. Walsh, Montreal; C. H. Mitchell, Toronto; A. M. Beale, Ottawa; B. E. Norrish, Ottawa; L. M. Edwards, Toronto; A. E. Brooke, Toronto; John Kennedy, Montreal; J. J. Salmond, Toronto; Prof. C. H. McLeod, Montreal; J. K. Scammell, St. John, N.B.; E. C. Keefer, Toronto; Alexander McDougall, Ottawa; A. A. Dion, Ottawa; H. A. Burson, St. Catharines; Wm. Storrie, Ottawa; C. O. Wood, Ottawa; F. H. Byrne, Ottawa; C. A. Bigger, Ottawa; J. B. Challies, Ottawa; R. Steckel, Ottawa; F. H. H. Williamson, Ottawa; R. F. Davy, North Temiskaming; A. G. Genest, Ottawa; Sidney B. Johnston, Ottawa; C. V. Johnston, Ottawa; E. V. Johnston, Ottawa; O. Higman, Ottawa; J. B. Hunt, Ottawa; W. S. Lawson, Ottawa; A. C. St. Laurent, Ottawa; V. Valiquet, Ottawa; Alexander Bailey, Ottawa; J. P. Laforest, Hull; G. G. Gale, A. E. Smaill, Ottawa; N. Cauchon, Ottawa; J. T. Farmer, Montreal; H. A. Woods, Montreal; C. D. Sargent, Cornwall; J. H. Garbden, Montreal; J. T. Johnston, Ottawa; M. C. Hendrie, Ottawa; W. F. M. Bryce, Ottawa; C. H. Attwood, Ottawa; G. H. Ferguson, Ottawa; G. P. Hawley, Cedars, Que.; W. D. Bergman, Montreal; K. M. Cameron, Ottawa; M. F. Cochrane, Ottawa; E. S. Mills, Ottawa; J. H. Brace, Cedars, Que.

INSURANCE ENGINEERING.

Considerable interest has been awakened in engineering and manufacturing circles in Canada by the formation at Montreal of a firm that might be called insurance consulting engineers. Just as other consulting engineering firms specialize in various branches, such as waterworks, or bridges, or factory construction, etc., this firm specializes in expert insurance engineering knowledge.

The firm name is E. M. Sellon & Company, Limited, with offices at 136 St. James Street, Montreal, and the personnel of the board of directors is sufficient recommendation for a wide-spread knowledge of the firm in regard to the business they are undertaking. The directors are E. M. Sellon, M.I.E.E.; J. J. Creelman, Professor of Railway Economics at McGill University; and Mr. Lawford Grant, president of the Canadian British Insulated Company, and honorable secretary for Canada for the Institute of Electrical Engineers of Great Britain.

This firm considers that insurance is a science, and requires expert treatment. A skilled force of engineers and inspectors is maintained to advise in regard to the insurance of industrial undertakings. They inspect industrial risks at their own expense, and thus secure at first hand the full information which is necessary to obtain rating at the minimum tariff. Such inspection frequently enables the firm to make suggestions on fire protection which add security and more than pay for themselves. In these cases the client places the insurance through the firm in the same manner as it would be placed through any firm of insurance brokers.

When new construction is proposed, however, the firm places its knowledge of fire protection and of the many matters which govern insurance rating at the disposal of the engineers and architects who have charge of the construction, the insurance then also being placed with the firm in the usual manner. There is undoubtedly considerable opportunity for decided success for a firm in Canada specializing in this work, as the minimizing of the fire hazard, and the increasing of what might be called "fire-proofness," is a subject of vital interest to every manufacturer.

New Westminster ratepayers have approved by-laws aggregating nearly $600,000, as follows: street, $200,000; light, $40,000; waterworks, $45,000; schools, $55,000; sewers, $150,000; firehalls, $25,000; civic stables, $15,000; exhibition, $25,000.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

Book Reviews:

BOOK REVIEWS.

Manual of Public Utilities (first annual number). Published by Poor's Railroad Manual Company, 535 Pearl Street, New York; 1,924 pp. Price, $7.50, postpaid.

This manual is devoted entirely to statements of public service corporations, such as street railway, gas and electric light, water, power, telephone and telegraph companies. It is a record of about 8,500 corporations, or practically every public utility in Canada and the United States.

The general index contains the names of merged companies, with references to the companies into which they have passed. The balance sheets and income accounts of the more important companies are presented in comparison with those of other years, so as to show the rate and extent of growth and development, supplying thereby the necessary data upon which to form an opinion of the value of their securities.

The manual contains reference to a larger number of public service corporations and their standing than does any previously published work.

Emery and the Emery Industry. By A. Haenig. Translated from the German by Charles Salter. 104 pp.; 5 ins. x 7 ins.; 45 illustrations; tables; bound in imitation leather. Publishers, Scott, Greenwood & Son. London, England. Price, $1.50 net.

This little work in three chapters deals with the growth of industry of abrasives and grinding machines attendant upon the development of the machinery industry. A neat historical introduction is followed by a chapter on natural and artificial abrasives, together with considerable space devoted to carborundum—its properties, methods of manufacture, output, etc. Chapter II. enters upon the preparation and complete treatment of emery wheels and discs, taking into consideration hardness and grain of material, binding medium and allowable peripheral velocity, stability and capacity of grinders, and points in their mounting, use and experimental tests. The next chapter is based upon the various types of grinding machines and their special uses.

The book closes with a valuable list of references, for the most part from the German, and a very complete index. The volume is well printed and handsomely bound, and the subject matter has been treated in a clear and most interesting manner. It will be of value to all laymen, tradesmen and engineers in mechanical circles.

Steam Engineering. By W. R. King, U.S.N., Principal Baltimore Polytechnic Institute. Publishers, John Wiley & Sons. 450 pp.; 6 ins. x 9 ins.; cloth. Price, $4.00 net.

The number of books along this line is increasing with such rapidity that very much originality can scarcely be expected in any of them. The author of this book, however, does not claim originality for his work, but feels that the systematic arrangement and simplicity attempted are worthy of merit.

Considerable space has been devoted to each of the parts of a power plant, such as the boiler, the engine, the condenser, etc., and as the engine is a very vital and probably the most intricate part, the method of designing and testing it has been gone into with some detail. The action of the simple slide valve is explained, and an entire chapter is devoted to the use and construction of the Leuner valve diagram.

The design of simple and compound engines is discussed, together with the general advantages of compounding and the method of combining the diagrams of these engines. There is only one chapter devoted to the turbine, and one-half of this is devoted to the de Laval make.

A five-page chapter on Entropy does not seem to be of much assistance to the general policy of the book, owing to its brevity, and one feels that it should have been longer, or else entirely omitted.

The whole order adopted in the book is very unusual, but the matter contained should be helpful to those without a close technical knowledge of the science of steam engineering, and, on the whole, the work is sufficiently simple as to be very easily understood.

A Text Book of Thermodynamics. By James R. Partington, M.Sc. Publishers, Constable & Company. 542 pp.; 5½ ins. x 8½ ins.; cloth. Price, $4.20 net.

This book has been written with special reference to chemistry, and is a mathematical treatment of the science of thermodynamics, the illustrations and applications applying almost entirely to chemistry.

The first chapter on thermometry and calorimetry, which deals with such matters as thermometers and the specific heats of substances, is followed by two chapters discussing in some detail the first and second laws of thermodynamics, on which the rest of the book is naturally based. These laws are then taken up in their general applications to fluids, and following this two chapters deal with their special reference to the perfect and permanent gases and vapours.

The remaining half of the book gives the special applications of the science to chemistry, containing chapters on thermochemistry, gas mixtures, the general theory of mixtures and solutions, capillarity and absorption, the kinetic theories and other kindred subjects.

The work is very nicely gotten up, but, as the calculus has been freely used, the book would be of little value to anyone not having sufficient mathematical training. To the

advanced student, however, it should prove of considerable value.

Iron and Steel Constructional Work. By Karl Schindler. Translated from the German and adapted to English practice by Charles Salter. Publishers, Scott, Greenwood & Company, London, England. 140 pp.; 5 ins. x 7 ins.; 115 illustrations; cloth. Price, $1.00 net.

The book is divided into five sections, the first of which is devoted to cast iron and mild steel columns, with reference to calculation for compression, eccentric loading, etc. Tables of inertia of various shapes are given for each. Section II. deals with girders and beams and the methods of loading, girder connections, rivetted girders, and contains an additional chapter on floor construction. The next section comprises four chapters on roof construction, dealing with loads, roof principals and trusses, together with their calculations and details. The construction of iron staircases is dealt with carefully by precept and example. The last section of the book is devoted to skylights of various types, floor lights and glazed roofing. At the end are five-place logarithmic tables, antilogarithms, trigonometrical functions, tables of squares, cubes, etc., and of metric equivalents.

The book is carefully written, and forms a compact little structural handbook, with examples suitable for practical application. The illnstrations are clear and appropriate, and the notation used throughout conforms well with that in general use.

Resuscitation.—By Dr. Chas. A. Lauffer, Medical Director, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. Publishers, John Wiley & Sons, New York. 47 pp.; 4 in. x 7 in.; cloth bound. Price, 50 cents net.

This book includes a reprint of a paper on this subject delivered by the author before the Philadelphia section of the National Electric Light Association. The author, after explaining a number of successful results which have been obtained from employing resuscitation methods on men who were supposedly dead, gives a clear description of the mechanism of respiration, illustrating same by a number of views of the various parts of the anatomy.

The Prone Pressure, or Schafer, method of resuscitation which has been adopted by the National Electric Light Association, and a number of other engineering societies, is described in detail.

This book brings out in a clear, concise manner the necessity of people in general being versed in the principles of resuscitation, and clearly shows how they can become sufficiently learned to prove of valuable assistance in the ordinary walks of life.

Solution of Railroad Problems by the Slide Rule. By E. R. Cary, C.E., Professor of Railroad Engineering and Geodesy, Rensselaer Polytechnic Institute. Publishers, D. VanNostrand Company, New York. 136 pp.; 4 ins. x 6 ins.; cloth. Price, $1.00 net.

This work is a compilation for the use of the civil engineer of the many ways in which his slide rule can be of extraordinary benefit. Numerous illustrations, examples and formula display methods whereby the instrument may be used with comparative accuracy, and a great saving of time, in the laying out of simple, compound, vertical or easement curves, and turnouts. A chapter is also devoted to its application in computing earthwork.

The first chapter deals with the slide rule alone, its description and method of operating in the solution of problems in general. Throughout the remainder of the text and under headings stated above are forty problems accompanied by forty-three illustrations and numerous tables. The book closes with tables of contents and a series of 114 formulas bearing upon railway track work.

In the working of the decimal point the author departs slightly from the practice recommended by slide rule booklets of keeping track of it in each operation. He recommends a mental calculation to ascertain the position of the decimal point in the result. This is the practice of many slide rule users, its only disadvantage being liability to err owing to mental occupation upon other parts of the calculation. Again, the manufacturers' instructions are the quicker, and, on the whole, are to be recommended.

An engineer will find the book of great use to him in railway work.

A Text-Book on Trade Waste Waters—Their Nature and Disposal. By H. M. Wilson and H. T. Calvert. Publishers, Messrs. Charles Griffin & Co., Limited, London, W.C. 450 pp.; 74 illustrations; 6 in. by 9 in.; cloth. Price, $4.50 net.

The book is written primarily from the standpoint of the sanitarian, and aims to show the means by which the waste liquids of industry can be disposed of so as to prevent pollution of streams or other sources of public water supply. However, with the characteristic thoroughness of English text-books the authors pay due attention to the commercial value of by-products, and fully discuss the various means that are adopted in order to recover materials of value from factory waste.

The book is technical, yet, owing to the many and various indnstries dealt with, peculiarly interesting. The plan throughout has been to describe the processes of manufacture which give rise to the waste water under discussion and to then describe the liquid and the treatment necessary. By this means the book becomes intelligible alike to layman and engineer.

"Trade Waste Waters" should prove valuable to all those who have the care of public water supplies, to the engineer who must advise them, and to the manufacturers, to whom it may mean not only the avoidance of a public nuisance but often a considerable economy of production. It brings into one volume the related matters of an extended literature, to which by copious bibliographies the reader is referred. The only exception that might be taken by a Canadian reader would be that the book relates almost wholly to English conditions and practice. English law in regard to stream pollution is the burden of practically two chapters. But even if in this regard it will not serve as a text-book of Canadian practice, that fact does not seriously detract from the value of the book.

Percentage Compass. For navigators, surveyors and travellers. By John C. Fergusson, M. Inst. C.E. Longmans, Green & Co., London, Eng. Unmounted, 75 cents; mounted, $1.10.

This comes in the form of a chart which is calculated to simplify the use of the compass and to effect a great saving in all angular computations. By means of this chart the surveyor and the traveller or the navigator can find as he goes along: First, the difference of latitude and departure: second, the closure angle of a compound traverse; third, the length of the closure line; fourth, by the use of the circular scale C it is possible to solve any problem in plain trigonometry by simple arithmetic. The percentage compass is a practical application of Fergusson's percentage unit of angular measurement of the magnetic compass dial, which converts it into a simple and accurate range finder.

PUBLICATIONS RECEIVED.

Annual Report of the City Engineer of Halifax.—Issued by the city of Halifax, N.S.

American Peat Society.—Ninety-eight page journal issued by the Society, Toledo, Ohio.

Works Administration.—28-page pamphlet issued by the Gunn, Richards & Company, New York.

Canadian Forestry Journal.—Pamphlet issued by the Canadian Forestry Association, Ottawa, Canada.

Some Mistaken Popular Notions Concerning Public Service Corporations.—By Frederick Strauss. Issued by the J. G. White Companies, New York.

Permissible Explosives.—Technical paper No. 52, by Clarence Hall. Issued by he Bureau of Mines, Department of the Interior, Washington, D.C.

Patents.—Official journal of patents of Great Britain, for June, 1913. Issued by the Patent Office, Southampton Building, Chancery Lane, London, W.C. Price, 6d.

Ohio State Board of Health.—April bulletin issued by the Board of Health, and contains interesting papers read before the Board by well-known medical men.

Properties of Saturated and Superheated Ammonia Vapor.—96-page bulletin by G. A. Goodenough and Wm. E. Mosher. Issued by the University of Illinois, Urbana, Ill.

Apparatus for Gas-Analysis Laboratories at Coal Mines.—Illustrated technical paper by G. A. Burrell and F. M. Seibert. Issued by the Bureau of Mines, Washington, D.C.

Magnetic Iron Sands.—Report by George C. MacKenzie, B.Sc., dealing with the investigation of the Natashkwan magnetic iron sands. Issued by the Department of Mines, Ottawa.

The Flash Point of Oils.—Technical paper dealing with methods and apparatus for its determination, by T. C. Allen and A. S. Crossfield. Issued by the Department of the Interior, Washington, D.C.

Mineral Production of Canada.—Annual report by John McLeish, B.A., containing revised statistical information descriptive of the mining and metallurgical production in Canada during the calendar year 1911. Issued by the Department of Mines, Ottawa.

American Wood Preservers' Association.—480-page booklet containing the proceedings of the ninth annual meeting of the American Wood Preservers' Association, held at Chicago, Ill. Issued by the society. F. J. Angier, secretary-treasurer, Baltimore, Maryland.

Report on the Livingstone Channel.—Contains the recommendations in reply to questions submitted by the Governments of the United States and Canada in regards the Channel. Issued by the International Joint Commission, Washington, D.C., and Ottawa, Ont.

Repair and Maintenance of Highways.—72-page illustrated bulletin by L. T. Hewes, Ph.D., dealing with the repair and maintenance of macadam roads of all kinds, gravel, sand-clay, and earth roads. Issued by the Department of Agriculture, Washington, D.C.

Minority Opinions, Kettle.—Bulletin dealing with dissenting opinions in regard to application of the Rainy River Improvement Company for approvement of plans for a dam at Kettle Falls. Issued by the International Joint Commission, Washington, D.C., and Ottawa, Ont.

Testimony in the Livingstone Channel.—225-page bulletin containing the references of the Governments of the United States and Canada under Article IX. of the treaty of May 5th, 1910. Issued by the International Joint Commission, Washington, D.C., and Ottawa, Ont.

Hearings and Arguments re Kettle Falls Dam.—128-page bulletin containing the hearings and arguments in the matter of the application of the Rainy River Improvement Company for approval of plans for a dam at Kettle Falls. Issued by the International Joint Commission, Washington, D.C., and Ottawa, Ont.

Highway Improvement.—Annual report of W. A. MacLean, chief engineer of highways, relating to highway improvement in the Province of Ontario, and containing the latest information on road construction, road metal, highway bridges and culverts, with illustrations. Issued by the Department of Public Works, Toronto, Ont.

The Year Book, 1912.—Containing the sixth annual report of the Council and transaction for 1912; also trade reports. Swedish traffic questions, with maps inserted of the city of London, railway and canal of Sweden, Blyth harbor, Port of Sutherland, River Tyne, Hartlepool docks, Hull docks, Immingham new dock and Port of Great Grimsby. Issued by the Swedish Chamber of Commerce in London, England.

Report of Water Commissioners, London, Ont.—Thirty-fourth annual report of the officials of the waterworks and electrical departments for the year ending November 30th, 1912, and the parks department for the year ending December 31st, 1912. It includes the general manager's reports and secretary's detailed statement of receipts and disbursements. Issued by the Waterworks, Electrical and Parks Department, London, Ont.

Cheap Steam and Machine-Firing.—A 27-page illustrated pamphlet dealing principally with the application of independent buckets, elevators and shoots to feed the stokers; construction and operation of the Gold Medal machine stoker; shows arrangement of machines for gas-firing as an alternative to coal-firing, and report of actual tests. Steam users will find drawings of the leading types of boilers especially interesting. Issued gratis to steam users by G. H. Tod, Manning Chambers, Queen Street West, Toronto.

CATALOGUES RECEIVED.

The Valve World.—Nicely illustrated catalogue. Issued by the Crane Company, Chicago, Ill.

Tobin Bronze.—Illustrated catalogue issued by American Brass Company, Ansinia Brass and Copper Branch, Ansinia, Conn.

Electric Service Magazine.—15-page illustrated catalogue. Issued by the Toronto Electric Light Company, Limited, Toronto.

Electric Arc Welding Apparatus.—Illustrated catalogue. Issued by the C. and C. Electric and Manufacturing Company, Garwood, New Jersey.

Labor Saver.—Illustrated catalogue on the efficiency and economy of production. Issued by the Stephens-Adamson Manufacturing Company, Aurora, Ill.

Sockets and Receptacles.—Third edition of supply catalogue, illustrated, contains 64 pages. Issued by the Canadian General Electric Company, Toronto.

Fuel Costs.—Eight-page pamphlet dealing with comparison of oil, gas and coal as a fuel. Issued gratis by the Tate-Jones & Company, Inc., Pittsburg, Pa.

J.-M. Packings and Specialties.—132-page, nicely illustrated catalogue, dealing with J.-M. asbestos products. Issued by the Canadian H. W. Johns-Manville Co., Limited.

Weber Chimneys.—48-page illustrated catalogue dealing with Weber coniform chimneys and methods of construction.

May be obtained on application from Weber Chimney Company, Chicago, Ill.

Robb Engine Boilers.—Illustrated catalogue in unique and original style. Issued by the International Engineering Works, Limited, formerly the Robb Engineering Company, Amherstburg, N.S.

Pneumatic Drills, Reamers, Wood Borers, Flue Rolling and Tapping Machines and Grinders. Illustrated catalogue. Issued by the Chicago Pneumatic Tool Company, Fisher Building, Chicago, Ill.

A Test by Technologists.—Contains the expert reports on the six years' weather tests of paint for steel on the Pennsylvania Railway Bridge at Havre de Grace, Md. Issued by the Lowe Bros. Company, Dayton, O.

The Road Models of the Office of Public Roads.—Descriptive catalogue illustrating the standard types of model road construction which represents the modern ideas of highway engineers. Issued by the United States Department of Agriculture, Office of Public Roads, Washington, D.C.

Chicago Pneumatic Tool Company have issued bulletin Nos. 128, 132 and 133 dealing with miscellaneous equipment of pneumatic drills, pneumatic motors and geared hoists and cylinder air-hoist and jacks, respectively. These may be obtained from the company, Fisher Building, Chicago, and 50 Church Street, New York.

The Purification of Water Supplies.—70-page illustrated catalogue containing a concise resumé of the nature of impurities usually found in natural water supplies and the modern methods adopted for effecting their removal. Deals with the physical characteristics of water, its impurities and quality in regards industrial purposes, methods of purification by storage, advantages and disadvantages of slow sand filtration, the advantages of the rapid system of filtration in general and the Paterson rapid system of filtration, gravity filter for industrial purposes, and the Paterson system of softening, sterilization and removal of iron in particular. Issued by the Paterson Engineering Company, Limited, 12 Norfolk Street, Strand, London, W.C.

NEW BOILER REGULATIONS FOR ONTARIO.

Following an act passed by the Ontario Legislature two sessions ago, regulations affecting the construction of boilers are to be brought into force on July 1st. Mr. D. M. Medcalf, who is public inspector of boilers for the province, has drafted regulations under the act which will henceforth compel manufacturers of boilers to submit plans and specifications to this branch of the Department of Public Works to insure a standard in both material and method of construction.

The regulations provide that all new boilers to be constructed in the province shall conform to a proper standard; second-hand boilers to which extensive repairs have been made will also be inspected. Until the present time practically any class of construction would go in the province, and boilers have been sold indiscriminately that have raised the danger risk to such an extent that human life has been impaired.

Twenty-four hundred miles of telephone wire will be strung by the employees of the Alberta department of telephones on rural lines this year, in addition to a large amount of long-distance line in construction and new exchange work in the growing towns and cities of the province. Over two million dollars will be expended by the government in extending the telephone system of Alberta during the year. At the beginning of the year there were in wire miles 9,671 miles of rural lines and 6,689 miles of long-distance telephone lines in **Alberta.**

COAST TO COAST.

Edmonton, Alta.—After examination into the possibilities of Rabbit Hills as the future source of a gravity supply of water for the people of the city of Edmonton, the commissioners have reported to the city council that they are not at all favorably impressed with it, but have faith in the present system proposition. First of all the Montreal experts, whose services in connection with their report on the city's water system cost $15,000, suggested that the plant at the present site be improved and extended to take care of Edmonton's requirements, now and for the future. That recommendation was turned down by the council owing to the fear that at some time heavy floods might submerge the flats and render the pumping and power station situated thereon useless, thereby depriving the citizens of light, power and water at one fell swoop. It was then decided to accept the second suggestion of the experts, namely, to look to Rabbit Hills as the source of supply, and the commissioners were instructed to prepare surveys and plans of this system. This they have apparently done, with the result that they have advised council not to proceed with its intention to obtain the city's water supply from that source, but rather to transfer their choice to the Beaver Hills proposition. When this report was read at a recent meeting of the council the members of that body seemed at first too taken aback to say very much, though some scathing criticisms of the commissioners were forthcoming later. Finally, on the motion of Ald. Tipton, it was agreed to instruct the commission board to proceed with their work of preparing plans and surveys of the Rabbit Hills scheme as set forth in the report of the Montreal experts, and as endorsed by resolution of the city council.

Saskatoon, Sask.—Although Saskatoon has cheaper steam-generated electric power than any other city in the prairie provinces, the city commissioners are taking steps to secure electricity at an even cheaper rate. The necessity for this is greatly emphasized by the government's announcement of the location of an interior storage elevator at Saskatoon. As the structure now to be erected, a five-million-bushel elevator, is but the first unit of what will eventually be an institution with a capacity of upwards of twenty-five million bushels, and as its establishment must of necessity tend to the development of the milling industry, and as a vigorous campaign for the securing of manufactories for Saskatoon is now in progress, the benefit which will accrue from any saving in the cost of power may readily be imagined. Commissioner Yorath, who has specialized in power problems, states that he has very definite prospects for cheaper power, these including three distinct propositions; one of these involves the generation of power at a point some 125 miles from Saskatoon and its transmission to the city; another includes possibly a more pretentious scheme which is being taken up with certain interests in London, Eng., and a third proposal, details of which are being considered.

Quebec, Que.—Honorable J. F. Caron, Minister of Agriculture, is very pleased with the results obtained so far through the policy of the good roads. There are fifty-eight gangs working at various points of the province, and all are going fast with the improved machinery supplied to them. The number of municipalities asking for money grants is ever on the increase and a sum of $5,000,000 has been paid by the government to the towns, villages and municipalities desirous to improve. This sum is exactly half the credit effected last year to these improvements. This sum, of course, does not include what the government is spending on large national roads. The Edward VII road will be the first com-

pleted, and the road between Montreal and Quebec is under way, the contractors having begun work from the western end of the road at Charlemagne. The road between Montreal and Ottawa will probably be built on the south bank of the Ottawa if the Province of Quebec can make arrangements with Ontario to build from St. Eugene to Ottawa.

Halifax, N.S.—Halifax has reason to be proud of and satisfied with the purity of its water. A sample was sent last month to Dr. J. T. Donald, Ottawa, official analyst to the Dominion Government. He was asked to make an analysis of the water as regards its suitability as a boiler feed water. Dr. Donald's reply was highly complimentary as to the value of the water for drinking purposes, with a report also regarding its use in boilers: "This is a remarkable water, containing as it does less than two grains of mineral matter per Imperial gallon. It is thus a very pure water. It is just possible it may be too pure for satisfactory use in boilers. We have had cases where a water with so little mineral matter had caused pitting and corrosion of tubes. This tendency was overcome by adding a small amount of lime to the water. If you will give us further particulars if you have any trouble in using this water we shall be glad to discuss the matter with you."

The analysis from a sample containing 10.5.13 was as below:—

	Grains per gallon.
Total solids	1.82
Sodium chloride	0.82
Carbonate of lime	0.25
Carbonate of magnesia	0.08
Iron oxide and alumina	0.11
Organic matter, etc.	0.56

Toronto, Ont.—The great host of Ontario people who yearly flock to the summer resorts of the north and the watering places about the fresh water system will this season enjoy a more adequate protection from unsanitary conditions than ever before. The efforts of the provincial board of health, which have been bent for several years towards the enforcement of efficient and cleanly methods of sewage disposal and water supply, are beginning to bear fruit. Dr. J. W. S. McCullough, chief health officer of Ontario, states that one great source of contamination has been removed in the adoption of high-class sewage systems on board the tourist steamers in the inland lakes. Five of these boats which ply constantly from point to point in the Muskoka region have installed septic tanks, and the intention of the department is that by next year every tourist line will be asked to submit to similar arrangements. Apart from the ordinary reaction of chemicals, which is set at work in all such plants, the additional precaution of turning live steam into the compartments for disinfection purposes will be followed. In this way no possible complaint as to the contamination of the water in the narrower channels or bays can occur in future. The general inspection of the cottages and hotels in the different parts of the province is being carried on at the present time. Owing to the activity of the department last year in forcing negligent proprietors into line, more satisfactory conditions are being experienced by the officials this year. District Officer Clinton, of Belleville, has completed an investigation of the Kawartha Lake region and with few exceptions has approved the methods. The Grimsby and Burlington Beaches at the present time are undergoing the investigation of Dr. McLenahan, of Hamilton, the board representative in that district. Because of the popularity of these places with a large class of people who cannot journey far from city life, the conditions are more congested. In consequence more difficulty is found in maintaining proper sanitary conveniences. A willingness to comply with the new regulations is now being met by the department, however. The installation of the new tanks on board ship was largely at the instigation of the shipowners, and hotel proprietors are gradually assuming the same attitude of co-operation.

Ottawa, Ont.—A party of surveyors is being sent out by the Public Works Department to prepare contract plans for the improvement to the French River in connection with which a vote of $500,000 was made at the last session. The river connects Georgian Bay and Lake Nipissing and would be one of the main sections of the Georgian Bay Canal if that great work were undertaken. Even if it were not, the improvements contemplated would facilitate navigation to the North Bay terminals from the Great Lakes. The principal improvements necessary are a system of controlling dams to regulate the level of the lake and two or three locks. The vote made last session is sufficient for carrying out the preliminary details and commencing construction. With regard to the Georgian Bay Canal project, it is intended, as announced by Hon. Mr. Rogers, to appoint a commission to enquire into the commercial feasibility of the project. From an engineering point of view, the feasibility of the undertaking has been fully established, but there is a singular lack of information as to the extent to which the canal, when built, would be utilized and become one of the great transportation routes of the country, as it is destined to be. It is not certain as yet as to when the commission will be appointed, but when it is, different parts of the country will be visited and evidence taken. Upon the report which is made will depend very largely whether or not the proposition will be gone ahead with by the government.

St. Boniface, Man.—In reference to the notice received from the Canadian Federation of Boards of Trade, the St. Boniface board have voted to support the Georgian Bay Canal scheme in opposition to the scheme of the United States to divert the great waterway to the United States waters, the Canadian plan calling for an expenditure of $75,000,000, as against the United States scheme of $51,000,000. The St. Boniface board is pledged to use its influence in favor of the Georgian Bay Canal, and to urge its members of parliament at Ottawa to support the project in the House.

Ottawa, Ont.—A peculiar case of unsatisfactory tenders is now before the Government, and after some weeks' consideration is still undecided. It is a contract for a building costing a million and a half dollars. Tenders were invited and received, but the lowest one was $200,000 below the estimate and $500,000 below the other bids. It came from a new and inexperienced firm, though accompanied by a heavy deposit cheque. New tenders were called, and instead of dropping out, the contractor has practically repeated the offer. The next lowest tender is from a firm whose work is very unsatisfactory. The situation is a delicate one because the work is being held back, and if the usual custom of accepting the lowest tender or the next one above is not followed there will be criticism. All of the big and reputable firms are away above the others. Meanwhile nothing is being done, and what solution will be arrived at is uncertain.

Victoria, B.C.—Four Cabinet Ministers will visit Victoria this summer, namely: Hon. Robert Rogers, Hon. J. D. Hazen, Hon. H. P. Pelletier and Hon. W. T. White. Mr. Rogers' visit is, of course, the most important, as under his department comes the work of construction of the Victoria harbor works and the Esquimalt drydock. The plans for the breakwater and piers for Victoria are being prepared by the Engineering Department of the Public Works at the present time, and the call for tenders will be issued within

a few weeks. As for the Esquimalt drydock, which will be included in part of the permanent naval policy of the Government, nothing can be done until a complete survey is made of the harbor. It is understood that a party will leave at once to undertake this work; and Mr. Rogers states that construction will be rushed with all possible speed.

Saskatoon, Sask.—According to civic authorities, cheap power is the chief requirement of Saskatoon to make it a milling centre. If a low rate of power is obtainable, it is only a matter of a short time until large mills will be under construction. It is understood that Hydro-Electric developments are shortly to receive consideration. It is the opinion of several engineers around the city that to make the power scheme profitable two dams will have to be built in the river. The Saskatchewan River probably carries more sand down with it than any other river in the Dominion. The idea now is to build a dam far up the river in the neighborhood of Pike Lake, which would act as a breakwater and hold all the silt which would otherwise drift down the river and form against the real dam, which is to supply the head water, which will make the wheels go round. If this is not done all the sand silt will form a drift up against the real dam, and thus spoil the head of water to a material degree. It is now seven years since Saskatoon first investigated the potentialities of the South Saskatchewan River with a view of producing power. At that time Saskatoon paid Engineer Mitchell, of the Ontario Hydro-Electric power scheme, $800.00 to report on the conditions of the river in the Saskatoon district with a view to securing the best of the different power sites in the vicinity of Saskatoon. There is a chance, on the other hand, that the visit to Prince Albert may mean the re-opening with that city of negotiations to take a block of power from their power-house at LaColle Falls. This opportunity was given to Saskatoon some time ago, but the city fathers did not embrace the scheme very heartily. If this is done, a right-of-way will have to be purchased between her and the site of the falls, a distance of something over a hundred miles.

Fort William, Ont.—Good progress is being made by the 200 men, who, with about 40 teams, are clearing and grading roads in the district for the Ontario Government. At present some 80 men and 30 teams are engaged on the Oliver Road, about two miles from Port Arthur. The men in charge of the work report that no unlooked for obstacles have been met with. Another large crew of laborers are working on the Pigeon River Road, which is ultimately to connect Fort William and Port Arthur and Duluth. It is intended to have the Pigeon River Road cleared and graded as far as the Minnesota boundary line this fall. Work on the continuation of the highway has been commenced in Cook County, Minn.

Vancouver, B.C.—"Switzerland annually receives millions in revenue from her mountain scenery and I see no reason why we should not do so within the next few years," said Col. R. E. Thomson, provincial engineer of Strathcona Park at the Progress Club recently. There was, he added, everything in the island area that would appeal to the mountain climber. There were peaks of great height, crevasses, glaciers and "chimneys," a rather narrow opening in the rock in which mountain climbers delight. Strathcona Park, he said, would be made a place to which tourists the world over would be attracted. Camping places along the sides of the many lakes would be improved and put into proper condition. The large number of small lakes just west of the Beaufort range of mountains would be surrounded with camping settlements. Here children would be able to play close to nature, while all kinds of outdoor sports could be indulged in. The land would be piped, thus assuring the campers of an adequate water supply and of a pure quality. The beaches about these lakes would furnish admirable places for bathing and swimming, while boating, canoeing and other aquatic sports would be fostered by the tranquil stretches of water which reflect the mountains close by. It is the purpose of the government, said Col. Thomson, to preserve all the curiosities of nature that would be found. Beaver dams and the work of the animals would be kept intact, so that people might see the real work of these creatures. The big trees which are in some cases over thirteen feet in diameter, would be left standing and proper supervision exercised to see that they were protected. Employees of the Strathcona Park, are now experimenting with flowers from the Himalaya Mountains to see if the same shrubs and roots can be grown in this province. The flora in the park would, he thought, equal that about Mount Rainier to the south. Nowhere could the wishes of the alpine climber be better satisfied than in Strathcona Park.

PERSONAL.

MR. T. F. SUTHERLAND, assistant inspector of mines, now resident in Cobalt, comes to Toronto on July 1st to assume his duties as chief inspector of mines for Ontario.

MR. A. P. HAZEN, who has been in the employ of the Dominion Government at Ottawa, on the design of the Port Nelson terminal of the Hudson Bay Railway, has just resigned.

PROF. V. I. SMART, of McGill University, department of railway engineering, is leaving to assume the position of general manager for the General Railway Signal Company, of Canada.

MR. D. W. McLAUGHLIN, of the engineering staff of the Hudson Bay Railway, has just left for Port Nelson to conduct survey work in connection with the establishment of the railway's terminals at that point.

MR. E. T. CORKILL, who has been chief inspector of mines in Ontario for some years, has just accepted a position with the Canadian Copper Company, at Copper Cliff. The office is that of safety engineer, and is the first of its kind in Ontario.

MR. GEORGE IRVING has been appointed Canadian manager for the National Meter Company, of New York, and not Mr. George Irvine, as stated in a recent issue of *The Canadian Engineer.* Mr. Irving will make his headquarters at 229 Spence Street, Winnipeg.

MR. R. E. HORE, Mem. Am. Inst. M.E., and for some years instructor in Geology and Petrography, Michigan College of Mines, succeeds Mr. J. C. Murray, resigned, as editor of the "Canadian Mining Journal," Toronto. He graduated from the University of Toronto in 1905.

MR. J. G. SEYFRIED, structural engineer and assistant to the chief engineer, Grand Trunk Railway, at Montreal, has resigned to accept an appointment as engineer, Bridge Department, Canada Foundry Company, Limited, Toronto. Mr. Seyfried will have charge of the designing and estimating, and will become assistant to the manager of the Bridge Department, Mr. J. L. Brower, M.C.S.C.E.

HON. LOUIS CODERRE, secretary of state, who is now also minister of mines, that branch having been recently transferred to his portfolio, has decided this summer to make an extensive western trip, going as far as Dawson City. Mr. Coderre will travel west with the delegates of the International Geological Congress, which meets in Toronto in

August. He will visit all the important western mining centres and in that way will be able to make a personal study of the needs of the department, and to become intimately acquainted with the mining resources of the country.

MR. ARTHUR S. HERBERT has resigned his position as general manager of the Siemens Company of Canada, Limited, and has been appointed general manager of the branch offices of the Siemens Company in Australia. Mr. Herbert is now in England, but will return to Canada for a few weeks early next month, sailing for Australia from Vancouver about the end of August. He will be succeeded in Canada by MR. C. A. ABLETT, whose name has been closely associated with the electrification of the rolling mills in Europe during the past few years, and who recently made a brief investigation of the position of the large steel works of Canada with regard to electric drive. Mr. Ablett will take up his duties in Canada at the beginning of next month, but the appointment dates from the 1st inst.

COMING MEETINGS.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—The Twelfth Annual Meeting to be held in Canada during July and August. Opening day of the Toronto Session, Thursday, August 7th. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Annual Meeting in Regina September 16, 17 and 18. General Secretary, Major Drum, Ottawa; Local Secretary, Dr. Murray, Regina.

THE INTERNATIONAL ENGINEERING CONGRESS.—Convention will be held in San Francisco in connection with the International Exposition, 1915.

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held at Chicago, Ill., Feb. 16-20, 1914. Secretary, E. E. Kraus, Harrison Bld., Philadelphia, Pa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—176 Mansfield Avenue, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, A. B. Lambe, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Muckleston; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, P. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 534 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSIOCATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.
